BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID.
Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D.,
Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

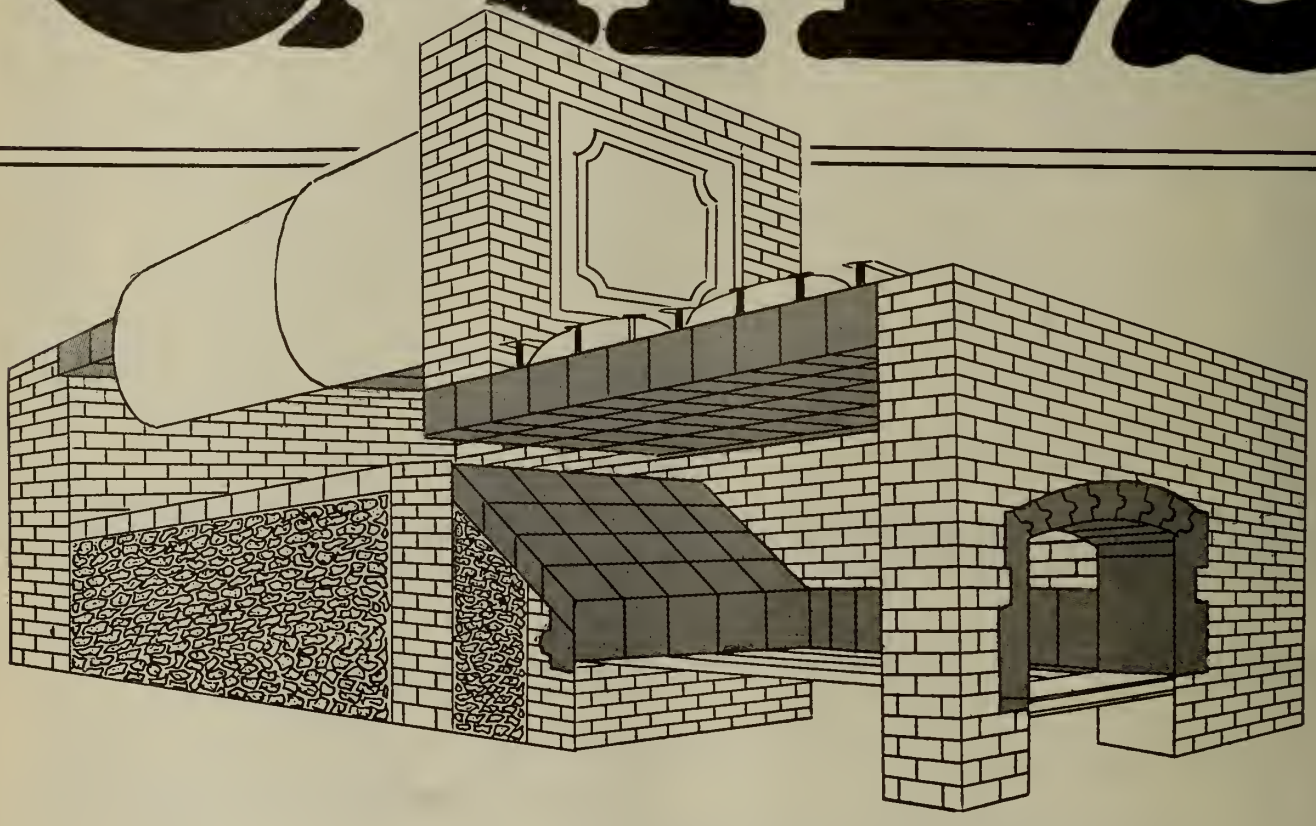
GATES



The Most Economical Boiler Setting

is the one that stands up the longest under all kinds of hard service. It should not need to be repaired frequently, because repairs are always costly, especially when they mean a boiler shutdown.

WE MANUFACTURE ALL

GATES REFRACTORIES, LIMITED,

PATENT ARCHES AND FURNACE LINING

Gates Suspended Arch

will do away with unnecessary repairs in the form of Blocks for Boiler Door Arches, Firewalls, Bridgewalls, Back Arches, Inner Arches, etc. It can be installed at the minimum labor cost, and it will last far longer than brick under average furnace conditions.

One of the special features of this arch is when any part becomes fused it can be replaced by any handy man without taking down the whole arch. *This means cutting your upkeep in boiler room* 50 *per cent.*

Our Stoker Arch is shipped from stock. There is no delay. Any boiler can be fitted accurately.

We contract for and specialize in Boiler Setting, Furnace Building, Oven Work, and all kinds of power plant brick work.

Our engineering department makes a study of each individual job. If stock on hand does not fit the case we will promptly design an arch which will not alone be a permanent fixture of the boiler or stoker, but which will materially better furnace conditions.

Call on our engineers at any time for information. Their services are offered to you without obligation on your part.

MAY WE SEND CATALOGUE?

"Silentic" Was a Bold Step in Naming

It is a name that stands for a guarantee of silence.

The Empire Manufacturing Company has never fallen down on a guarantee, we never will.

The "Silentic" is as near silent as any sanitary fixture can be. Every sanitary engineer who has installed "Silentics" is ready to back us in our guarantee.

Silentic-Plate A22-D.
Empire Vitreous China Double Wavered Lowdown Tank, white pyralin coated.
"Action D," and 2" white pyralin coated offset connection.

The scores of householders who have enjoyed the freedom from embarrassment, that the "Silentic" makes possible, are our best advertisement.

But silence is not the only selling point of the "Silentic." Note its handsome snow-white appearance——no nickel to tarnish and spoil its appearance. Like all our lines of plumbing, the "Silentic" meets every requirement. All our sanitary fixtures must be absolutely efficient, non-corrosive, durable, Sanitary or they do not leave our factory.

in a Jiffy

with

PYRO PUTTY

TRADE MARK REG U.S. PAT OFF

FIRE BRICK IN PUTTY FORM

The World's Best Furnace Lining Material

PYRO-PUTTY comes to you in a stiff, moist, pliable, "ready to use" condition. PYRO-PUTTY enables unskilled labor to make furnace lining repairs in less time and at less expense than would be possible with standard fire bricks. Simply clean out the breaks in the walls, pound in PYRO-PUTTY with a mallet, smooth it off with a trowel and you'll have a patch that will outwear the rest of the furnace lining.

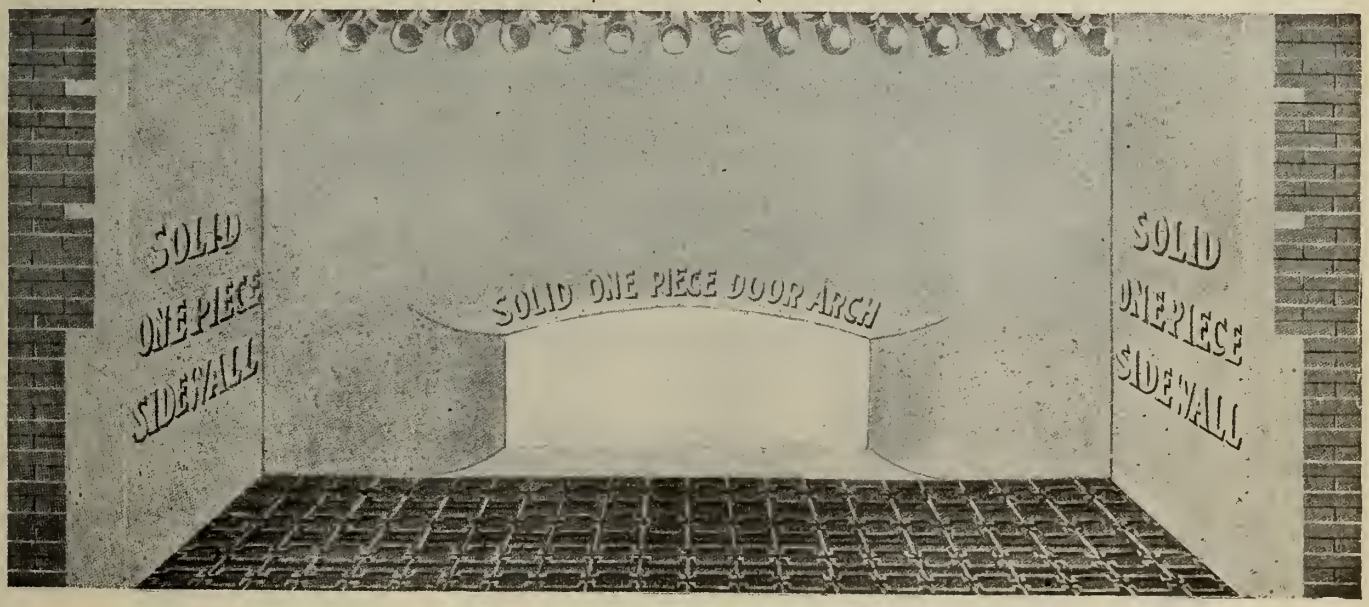
Pyro-Putty is far more durable than standard Fire Bricks for making New Furnace Linings

PYRO-PUTTY should be used, in preference to standard fire bricks, for making complete furnace linings because it is far more durable. And furnaces lined with PYRO-PUTTY are both efficient and economical because there are no joints to let the hot air out or the cold air in.

PYRO-PUTTY is put up in 700-lb. barrels, a barrel being equivalent to 100 standard fire brick. Sketch below represents the fire box of a water tube boiler lined with PYRO PUTTY. Compare it with your own fire box linings—then

ORDER A FEW BARRELS OF PYRO-PUTTY NOW!

"A few barrels of Pyro-Putty should be part of the emergency equipment of every steam power plant"



Sketch above represents the fire box of a water tube boiler lined with PYRO PUTTY.

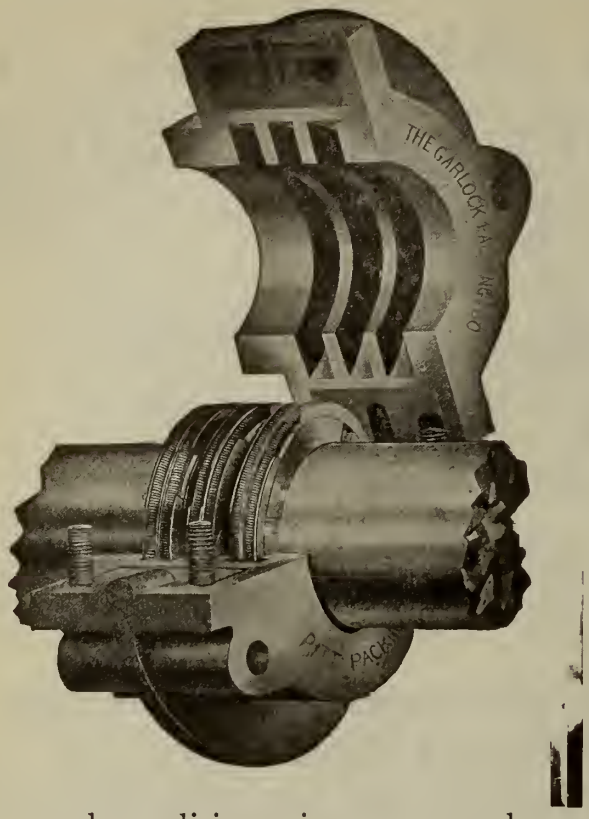
PYRO PRODUCTS COMPANY

P.O. Box 685, Toronto, Ontario



GARLOCK Metal Packing

OUR position in the metal packing field is based on the principle that "No one style of metal packing can be made to meet all conditions." Working on this basis our experts study carefully the conditions surrounding each case, and with strict regard for mechanical principles, determine which type of packing is best suited to the conditions.

¶ The accompanying illustration shows our Flexible Packing, with split case, which is the most popular style and best all-round packing for stationary work, and when recommended by us to meet stated conditions, is guaranteed to give satisfactory service. This style is also made with solid or split-case to fit inside of stuffing-box, when packing space is sufficient to permit inside application of case and segments. All of our metal packings are so designed that the piston rod has absolute freedom of lateral movement without affecting the efficiency or increasing the friction of the packing.

¶ Next to correct mechanical design the most important feature of metal packing is the material used in the bearing rings. Our materials are made from formulas which long experience has shown to give the best results. A special grade of cast iron is generally used for bearing segments, in order to secure minimum wear and friction, but under unusual conditions, or when considerable condensation enters stuffing-box, bronze rings or segments of softer metal have to be used in the wearing parts.

¶ We can solve your metal packing problems, and we will give the usual Garlock guarantee of satisfactory service, if conditions are such as will admit of the successful use of any metal packing.

Write for catalog describing our many styles of metal and fibrous packing.

Do you know that—

a hot surface of this measured area wastes 127½ pounds of coal each year?

Few people realize that this condition exists if the temperature within a pipe, for example, is 230° Fahrenheit (the temperature of steam at 5 lbs. pressure) and the temperature of the air surrounding the pipe is 70° Fahrenheit—a very moderate condition.

If it is steam heat—

Size of steam pipe.	
2"	$ .95
3"	1.40
4"	1.80
5"	2.20
6"	2.65

The waste in dollars per year per linear foot of pipe, coal at $10.00 per ton, 1 lb. steam pressure—temperature of air around pipe 70° Fahrenheit.

Read the remedy to the right.

If it is hot-air heat—

Size of hot-air pipe.	
8"	$1.00
9"	1.10
10"	1.25
12"	1.50

The waste in dollars per year per linear foot of pipe, coal at $10.00 per ton. Air in pipe 150° Fahrenheit—air around pipe 70°.

Read the remedy to the right.

If it is hot-water heat—

Size of hot-water pipe.	
2"	$ .67
3"	1.00
4"	1.25
5"	1.55
6"	1.85

The loss in dollars per year per linear foot of pipe, coal at $10.00 per ton. Water in pipe 180° Fahrenheit. Air around pipe 70° Fahrenheit.

Read the remedy to the right.

EVERY hot surface radiates heat. If this heat goes where it is not required, it is wasted and so is the coal that was burned to produce it. Opposite are some actual figures on such wastes—based on average conditions in American homes like yours.

The Remedy

Insulation correctly designed, manufactured and applied will reduce heat loss from hot surfaces as much as 90%. Efficient insulation must be made of material that does not conduct heat and that combines with this property the necessary strength and durability.

Johns-Manville Asbestocel Insulation has all these desirable characteristics. It is made for application to steam, hot-air and hot-water systems. Other Johns-Manville Materials: Sponge felt and 85% Magnesia for high pressure steam, Anti-Sweat and Zero for cold water, Combination Built-Up for Brine and Ammonia.

Inspect your heating plant for exposed hot surfaces on pipes, boilers and heaters, and for sections not *properly* insulated.

Have your steamfitter apply Asbestocel to pipes, boilers or heaters, sealing all cracks and joints, finishing boiler and heater surfaces with Johns-Manville Insulating Cement. In this way you will save the added coal that must be burned when there is waste.

CANADIAN JOHNS-MANVILLE CO., LIMITED

Montreal Toronto Vancouver Winnipeg Hamilton London Ottawa

Unfortunately many materials used for "covering" pipes are not efficient heat insulations — not only because their constituent materials are inferior, but because their construction is incorrect or faulty.

To aid you in buying, Asbestocel is shown here in two forms:

In sectional form for fitting around steam and hot-water pipes.

In flexible roll form, for fitting around hot-air pipes, heaters, etc.

We recommend Asbestocel rather than air cell because of its construction, viz: the cells run around the pipe—not lengthwise, thus preventing circulation of air.

Friction Surfacing Cuts Power Bills

Here is a statement that you can prove to your satisfaction and profit.

Take the meanest drives in your plant—the ones you know are wasting power in slippage on pulleys — ask our belting engineers to specify the correct size of

Dominion Friction Surface Belting

Keep a careful record of those belts for one or two months, or even a year, and compare it with the previous performance of those same drives—then compare *your* power bills for the two periods.

Dominion Friction Surface Belting will prove, in service, every claim we make for it, because the rubber with which it is saturated is a special friction compound that prevents practically all slippage and pays for itself in the power saved.

Our engineers are ready to help you, without charge, increase *your* production and lower *your* cost by making *your* transmission more efficient.

Phone or wire our nearest Service Branch.

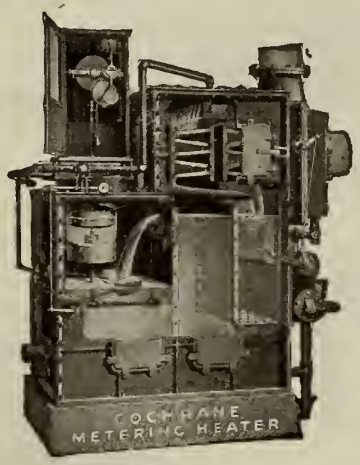
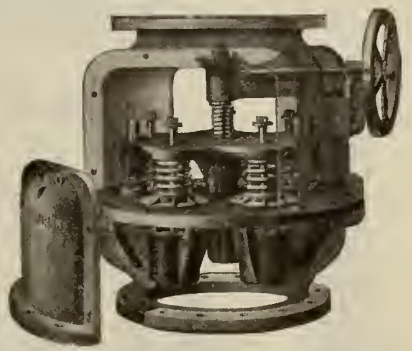
COCHRANE
COAL SAVERS

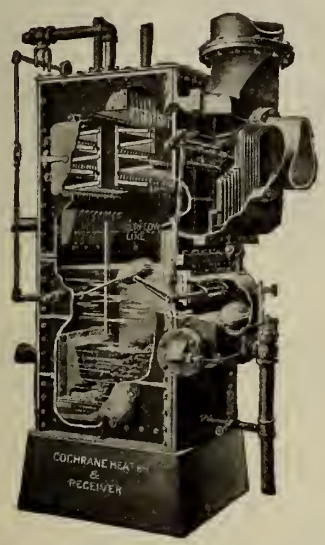
The Cochrane Oil Separator saves coal by rendering the exhaust steam useful for heating, drying and other purposes.



The Cochrane Metering Heater saves coal by heating the feed water and helps save coal by telling whether or not the plant is being operated economically.



The Cochrane Multiport Back Pressure Valve saves coal by preventing leakage of exhaust steam and by making it easy to adjust the back pressure whenever desired. The Cochrane Oil Separator saves coal by rendering the exhaust steam useful for heating, drying and other purposes.



The Cochrane Open Feed Water Heater saves coal by utilizing exhaust steam to heat the feed water; 1% saving for each 11° F. rise.

Canada is Saving Many Thousand Tons
of Coal Per Year by Using Cochrane Heaters

Here are the figures:

The **horsepower** of Cochrane Heaters in use is about 10,000,000 boiler horsepower.

The corresponding amount of **coal burned** is 35,000,000 lb. per hour.

Considering an average of 10 hours' operation per day, 300 days per year (many heaters run 24 hours per day, 365 days per year), this amounts to 105,000,000,000 lb. of coal per year, or 50,000,000 tons, worth at $5.00 per ton, **$250,000,000.**

The saving due to the use **of Cochrane Heaters** is 1% to each 11° F. rise in temperature. On the average, the water is raised from 100° F. to 210° F. using steam at atmospheric pressure, 10% or a saving of 10%. Cochrane Heaters are thus **saving about $25,000,000** per year, which is vastly more than the heaters cost.

In addition, Cochrane Oil Separators are saving millions of tons of coal by **purifying exhaust steam** so that it can take the place of live steam in heating and drying coils, low pressure turbines and industrial processes.

Sorge-Cochrane Hot Process Water Softeners are saving millions by **keeping scale and corrosive substances out of boilers** and thus saving expense and labor in cleaning boilers, and for new tubes and other boiler repairs.

Cochrane Metering Heaters are also telling hundreds of **steam-plant owners**, managers and operators how much **they are gaining in economy** by using different coals, different methods of firing, different methods of controlling the draft, stopping up air leaks in boiler settings, cleaning soot and scale from heating surface, etc. The total gains realized in this manner often amount to 25% or more.

Our engineering department has given hard study to fuel economy for over 25 years. It will be glad to aid you with suggestions if you will describe your present boiler feed water heating, softening, or metering arrangements, the amount of exhaust steam you have available and what you are using it for.

Ask for a book on "The Profitable Utilization of Exhaust Steam."

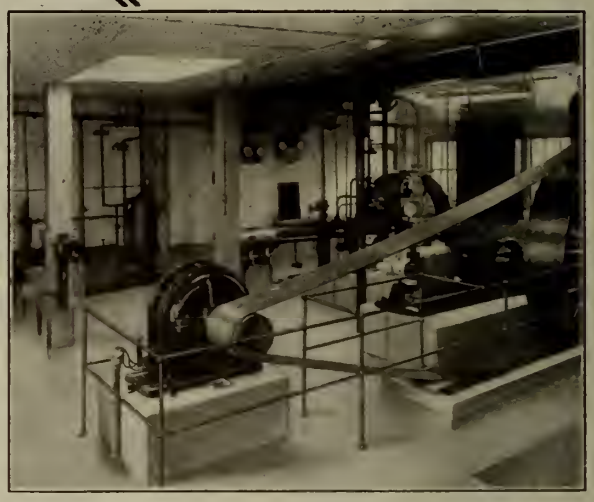
LINDE

REFRIGERATING AND
ICE MAKING MACHINERY

LINDE machines represent Quality and Service!

100-ton plant in operation.



Everything for Refrigerating and Ice Plants, large or small

Mechanical refrigeration scientifically applied means increased returns to the user. Increase your profits by installing LINDE system in place of unsanitary methods. LINDE (New) Vertical Enclosed Type Machines offer the most modern improvement and convenience for small plants from 1 to 30 tons. The large horizontal frame type guarantees unequalled service to users whose heavy demands calls for loads up to 300 tons.

Our engineering staff is at your service. Designs, specifications and estimates on request.

Every Part of Every FRICK INSTALLATION Must Be Perfect in order to maintain

FRICK SUPERIORITY

That is why Frick Refrigerating and Ice Making Equipment proves a profitable investment wherever installed.

The entire Frick line, from the smallest to the largest plant, from the smallest part to the largest part in each plant, is designed to meet our strict standard of Durability—Efficiency—Economy. Every part must be perfect in order to maintain the well-known FRICK Superiority.

Therefore, when you purchase FRICK Equipment you are assured of perfect service regardless of the unforeseen overload demand that might be placed on it sometime—assured of continued operation without danger of breakdowns in the midst of a busy season—assured of economical operation at all times—and a long life. Frick Equipment has been standing up under the above conditions for nearly a half-century, day after day, year after year, under the most severe conditions.

You can't go wrong when you specify "Frick Equipment." **Catalog on request.**

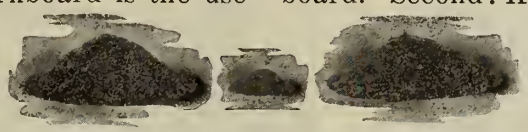
Corkboard that Is *All* Cork

One important thing to be observed in the manufacture of superior corkboard is the use of **clean cork only.** Nonpareil Corkboard, known to refrigerating men everywhere for its unique service records, is made of the best cork waste available, practically all of which is obtained from the plants operated by the Armstrong Cork Company in this country and abroad. By thus going back to the sources of supply, control over the quality of the raw material is assured.



Pile to the left, cork before being cleaned. Centre pile, screenings removed in the cleaning process. Pile to the right, clean cork—the only kind used in Nonpareil Corkboard.

There are two reasons why dirt should be scrupulously guarded against in the manufacture of corkboard. First: Foreign matter reduces the insulating efficiency of the finished board. Second: If the natural gum binder gets impregnated with dirt, it cannot perform its function properly, and the result is impaired durability.

Examine a sample of Nonpareil Corkboard critically. Break it in two and look at the fractured surface. You will find it to be clean and of uniform quality throughout. For all dirt, dust and fine particles were removed from the raw material before it was baked.

If you want corkboard that is **all cork** and **good cork,** insist on "Nonpareil."

Nonpareil Corkboard Insulation

For Cold Storage Rooms

Many owners, managers and superintendents of refrigerating plants have found answers to difficult questions in the 152-page book "Nonpareil Corkboard Insulation." Do you own a copy? If not, let us send you one. There is no charge for it.

Armstrong Cork & Insulation Company, 504 McGill Building, Montreal, Quebec, Canada

York Refrigerating Machinery

QUALITY—SERVICE

From the very beginning we have been building **quality** and **service** into our Refrigerating Machines. This has resulted in increasing sales of our products and increasing satisfaction on the part of our customers.

With a York Refrigerating Plant you can improve the quality of **your** product as well as the measure of service **you** render to your trade.

Any firm that installs a Refrigerating Plant is looked upon by the trade it serves as a progressive firm. Give MECHANICAL REFRIGERATION a chance. In these days of keen competition it is the progressive owner who survives and profits.

A Simple Design That Means Years of Reliable Service

The Yarway (formerly the Simplex) Seatless Blow-Off Valve is the last word in simplicity.

It consists of a hollow piston that is raised and lowered within the valve body. Study the illustration and description. Note especially how packing is automatically compressed when valve is closed, a feature that makes the Yarway leakproof. The protected position of packing prolongs its life to such an extent that renewal is necessary only at intervals of several years.

The large unobstructed port allows free uninterrupted passage to the blow down.

Try one for 60 days, subject to return. Write to-day, stating size of line and whether screw or flange, and angle or straightway.

GOODYEAR

MADE IN CANADA

Reduce Belt Replacement

Changing belts costs money.

Belts which wear out quickly must be replaced frequently.

This costs money for belting.

Costs money for idle machinery.

Costs money for idle hands.

Costs money because piece-workers become dissatisfied.

Goodyear Extra Power Belting reduces belting costs.

It wears long, and so makes the belting itself cost less.

It keeps machinery and men busy, and enables everyone to produce at greatest efficiency.

This has been the experience of every one of the more than a thousand Canadian plants which use Goodyear Extra Power Belting.

For example, here is what the Victoria Foundry Company, of Ottawa, say about their Extra Power:

VICTORIA FOUNDRY COMPANY, LIMITED, OTTAWA

Gentlemen:

We have certainly had great satisfaction from your "Extra Power" Belting.

We have used it on all kinds of machines. It has been in service a surprising length of time—and is still in service.

For instance—

16 months on the cone of a 30-inch Lodge & Shipley lathe.
18 months on the cone of a 24-inch lathe.
24 months on a 30-inch drill press.
12 months on main drive of a 36-inch planer.

And all still in service. Not a replacement so far. We are mighty pleased.

Yours very truly,

THE VICTORIA FOUNDRY COMPANY, LIMITED.

Men trained by Goodyear to solve belting problems are always available to confer with you. No obligation. Just wire, phone or write the nearest branch.

The Trueing of Commutators

The Second of Several Articles Descriptive of Commutators and Their Troubles. This Article Deals With Various Methods of Dressing and Trueing Up.

By W. F. SUTHERLAND

COMMUTATORS, like everything else, need care and attention, and at times, repairs of various sorts. Brush wear will often develop irregularities causing unevenness. A loose bar may creep out beyond the general surface of the commutator or the commutator may become excessively out of round or eccentric. Eccentricity in itself is not objectionable in slow speed machines, if present in small amounts. Many commutators operate when in this condition and give perfect satisfaction. In some cases it is only possible to correct this fault by trueing the commutator up when the armature is in its own bearings.

The above faults may be termed mechanical ones and other troubles of an electrical nature may necessitate corrective measures. Excessive sparking due to many causes will very quickly destroy the smooth polished surface which ensures sweet running. The causes of sparking in its many forms will be taken up in a later article, the present one being a resume of the various methods in current use for the restoring of a satisfactory surface when necessary from any cause.

For the above troubles a number of remedies may be used. Sanding may suffice when slight pitting has occurred, but when high bars are present, when the commutator is out of round, or when pitting is present in large amounts and of a severe character, it will usually be found necessary to resort to grinding or turning.

Turning Commutators

In turning commutators, the allowable peripheral speed will depend in large measure upon the condition of the commutator itself. If high bars are present the first cut should be made at a speed of about 100 ft. per minute. The finishing cut may be made at as high a speed as the tool will permit, up to 200 ft. per minute, with moderate and large size commutators. Speeds of 400 ft. per minute are sometimes reached in the turning of small commutators.

A high cutting speed and a sharp and carefully ground tool give the best results in machinery copper. The tool should be of the diamond shape and should be set as high above the centre as possible and yet cut with a clearance below the point.

The maximum speed used should be about one-thirty-second of an inch. Fig. 1 shows one of the best tools used for turning commutators, that recommended by the Westinghouse Co. This is a side-cutting tool with the point ground to about 1/16 in. radius. The cutting side and point should be given considerably more rake than is customary for use in working steel or iron.

Care should be taken to see that the tool is sharp enough to make a clean, smooth cut without dragging copper over the mica. The ends of the bars should be rounded off with a file while the commutator is in the lathe or after turning in its own bearings and while rotating at

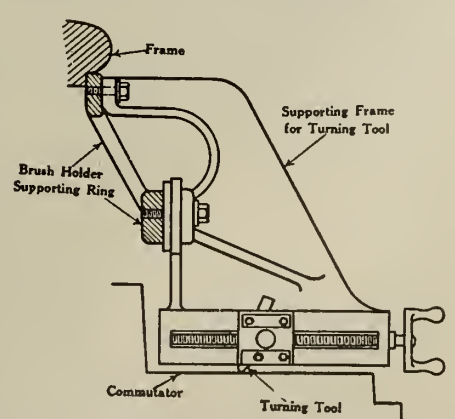

FIG. 1—ATTACHMENT FOR TURNING COMMUTATORS IN SITU.
—Courtesy Westirghouse Co.

the cutting speed. This rounding off should be done until the bars have a rounded corner of about 1/16 in. radius. The inner corner should also be rounded likewise as shown in Fig. 3. This is important, for if the commutator is

left with sharp corners at the ends of the bars, the mica is easily broken out and short circuits established by oil and dust at these points. After turning the commutator should be examined carefully to see that there are no small particles of copper bridging adjacent bars.

Before turning a commutator, a suitable head or cover should be made to prevent chips and dust from working into the armature. This head is best applied by taking a strip of cotton several inches wider than the length of the end connection and long enough to encircle the commutator, wrapping it around the commutator and binding the inside edge with cord as closely to the end connections as possible. The cord should then be turned up over the end connections and bound with cord to the outside of the armature.

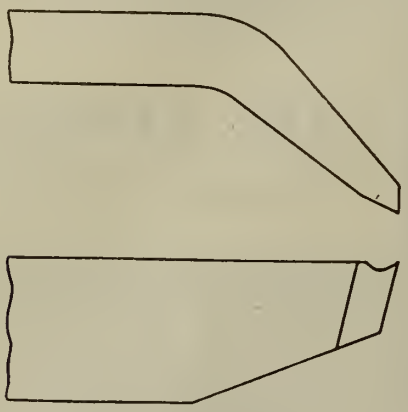

FIG. 2—TOOL RECOMMENDED FOR TURNING COMMUTATORS.

When turning a commutator with the armature in its own bearings some outside source of motive power is required if it is a motor that is being repaired. The power can most easily be obtained from a smaller motor conveniently placed and belted to the machine being worked upon. When turning the commutator of a generator, the engine can usually be speeded down to the proper number of revolutions per minute. Fig. 2 shows a turning device recommended by the Westinghouse Company and it will be seen that it is nothing more nor less than the familiar slide rest. A convenient lathe in the plant or in the engineer's own workshop can often be robbed of its slide rest and an attachment made for its support on the machine being worked upon. It must be kept in mind, however, that any support for the tool holder must be absolutely rigid and strong, for if the tool should dig in serious damage to the commutator will necessarilly result. The ways of the turning device should be set so that they are absolutely parallel with the commutator and securely fastened and braced.

It should hardly be necessary to reiterate the oft repeated advice—"Never lift the armature by slings around the commutator." This repetition may serve some useful purpose, for nothing will injure a commutator more; even if the surface be not marred, it will probably be forced out of round.

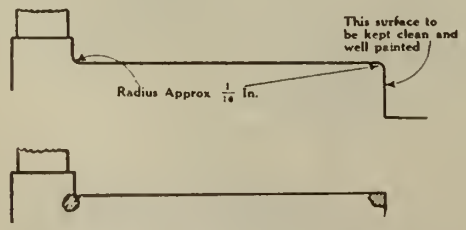

FIG. 3—SHOWING WHY CORNERS SHOULD ALWAYS BE ROUNDED AFTER GRINDING

Sanding

A commutator after having been freshly turned, is not in a fit condition to carry loads and it is necessary, in most cases, to sandpaper it before being put into service.

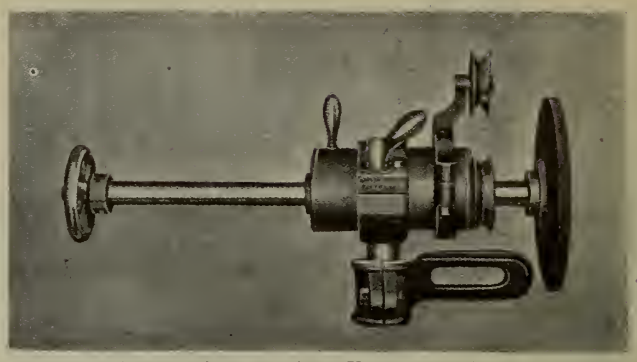

FIG. 4—JORDAN COMMUTATOR GRINDER.

The following hints re sandpapering also apply when it is desired to smooth the surface and thus remove any slight irregularities, such as pitting, etc.

If the surface is rough, No. 1½ paper should be used, followed by No. 1, and later by No. 00. Sandpaper should not be forced against the commutator by a lever, unless care is taken to distribute the pressure evenly over the whole of the paper. Many descriptions have appeared in the technical press of various sanding devices, but any engineer can make them to suit himself. One thing should be guarded against; the block should never be wedge-shaped so that it can be drawn into a brush holder bracket. If this occurs, a hurry-up repair job will be necessary and fireworks, of a verbal variety at any rate, will ensue. It it customary to mount the paper on a block, 15 or 20 sheets being screwed on to begin with, to give flexibility and an even distribution of pressure.

When the armature has been removed and placed in a lathe, the correct speed for sanding can easily be secured, and when it has been freshly turned in its own bearings, the same motive power used for turning will be available. Rotary convertor commutators are often sanded, brushes being of course removed, by starting upon the a.c. side and allowing the machine to run down to practically zero speed while sanding.

In finishing, one sheet of No. 00 paper should be used backed by felting or other suitable padding and the paper should be oiled with machine oil on the back. This oil will work through and will tend to catch the copper fragments and particles of sand, preventing them from being embedded in the mica. The surface of the commutator may then be polished with the back of the sandpaper or a strip of canvas.

It should hardly be necessary to repeat the warning often given: never use emery cloth or paper on commutators. Nothing will cause more trouble than this in operation, for the grains of emery will embed themselves in the copper with disastrous results.

Large machines are often shipped with the commutators freshly turned and after a commutator has been re-surfaced, it is also in a similar raw state. This condition and the fact that the brushes are either new or have been adjusted by sanding should be taken into consideration when putting the machine into service. If the machine is re-

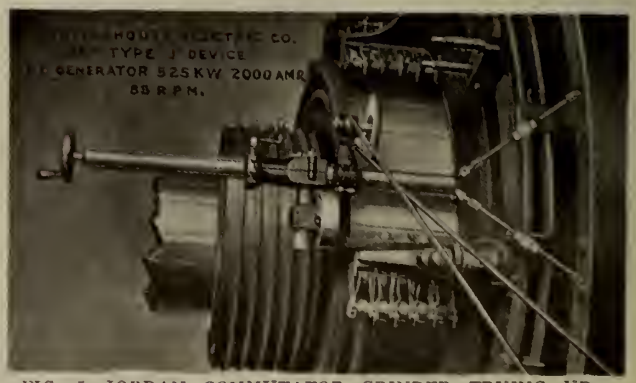

FIG. 5—JORDAN COMMUTATOR GRINDER TRUING UP COMMUTATOR ON WESTINGHOUSE MACHINES.

ceived with the commutator freshly turned, or if it has been refinished, it is advisable to run the machine light for some time, (one maker advising 24 hours), then at a load of about one-half full load for an equal length of time. This will polish the commutator.

A properly polished commutator will show a very high polish and will vary in color from a light straw to a dark brown, or even a blue gray, the actual color being of no importance. In the polishing of a commutator, no lubricant should be used.

Commutator Grinding

The turning of commutators has largely been superseded by grinding. This latter practice has much to commend it, for commutators can be trued up without removing the armature from its bearings and the machine can be run at its regular speed and can go on delivering power at the same time.

When turning up a commutator in the lathe, the motor or generator has to be shut down and the armature removed, possibly at the expense of some damage to itself. Copper may drag across the mica insulation and a considerable amount of material is removed. Turning with a portable slide rest suffers from the disadvantage of shutting down the generator or motor and running it at a reduced speed by some outside source of motive power. Difficulty is often encountered in securing a rigid support for the slide rest, failing which the tool is apt to dig

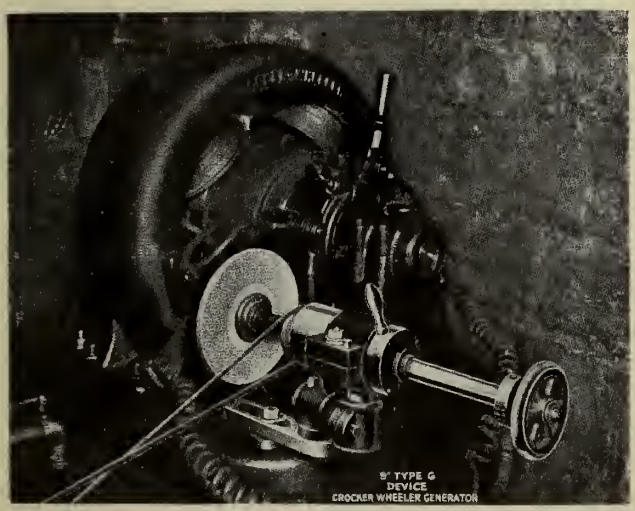

FIG. 6—SHOWING METHOD OF MOUNTING JORDAN COMMUTATOR GRINDER ON BED-PLATE.

into the commutator with disastrous results. End play of the armature in its bearings also has to be provided against.

By grinding a commutator it will last anywhere from two to three times as long, owing to the smaller amount of metal removed at each refinishing and sanding is unnecessary. The illustrations, Figs. 4, 5 and 6 show grinding attachments made by Jordan Brothers, New York, for the refinishing of commutators on all classes of direct current machinery.

Various types of this machine are in use, some belt driven, and some direct connected to a motor through a flexible shaft. The arrangement is simple, consisting in its essentials of a grinding wheel supported on a shaft running in ball bearings and with provision for adjustment radially to the commutator and lengthwise along the commutator face.

Special wheels are recommended by the makers of this device. Emery wheels won't do, owing to the conducting nature of the abrasive and to its tendency to embed itself in the copper surface. Wheels too hard or too soft are also unsuitable for the work.

In turning a commutator, the device is fastened in position so that its shaft is parallel to the generator or motor shaft, and the grinding wheel just clears the commutator. A round belt passes around a driving pulley

FIG. 7—USING THE IDEAL COMMUTATOR RESURFACER ON A SMALL MACHINE.

on the grinding wheel shaft and from there to a grooved pulley on a one h.p. motor. The grinding wheel is moveable parallel to the commutator and has sufficient range so that it can be fed across the entire width of the commutator face. The shaft in several of the various types of this machine is set in an eccentric barrel and by the manipulation of the handle controlling this eccentric barrel the wheel can be approached nearer the centre of the commutator, thereby taking off as light a cut as may be desired.

Re-surfacing by Abrasive Blocks

Another method for re-surfacing commutators has recently been developed. Blocks of abrasive materials of

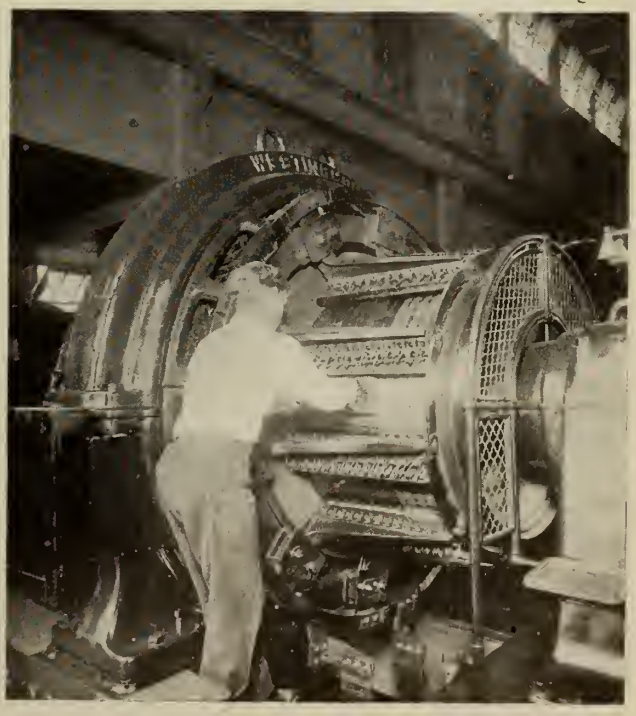

FIG. 8—RESURFACING ROTARY CONVERTOR COMMUTATOR.

FIG. 9—SLIP RINGS ARE EASILY TUNED UP.

the proper composition texture are used, fitted with suitable handles for convenient handling. Figs. 7, 8 and 9 show these re-surfacers, made by the Ideal Commutator Dresser Co., Chicago, in use. Fig. 7 shows one in use re-surfacing a small commutator, Fig. 8 shows a rotary convertor commutator being re-surfaced under load, and Fig. 8 shows its application to the a.c. collector rings of the same machine. The large re-surfacers for heavy work have double U handles, so that both hands can be used in controlling and supporting them.

As in the machine grinding of commutators, not every abrasive is suitable for use in these blocks, but artificial abrasives are used which are selected for characteristics suitable for the work.

Three grades are used, coarse for the removal of large amounts of copper, fine for the removal of high mica and small amounts of copper and extra fine for finishing purposes.

Many of the advantages which are inherent in the grinding of commutators by means of abrasive wheels are found in the use of these blocks. High mica, ridges and high bars are cut down, grooves and low spots smoothed out.

Making the Boiler Room a Safe Place to Work

The National Safety Council, Chicago, Issues Valuable Literature on Safety Practices in General. The following Article is Based on Their "Safe Practices for Boiler Rooms"

MANY potential causes of accidents exist in and around the power plant and particularly the boiler room. In carelessly kept boiler rooms the stumbling hazard is present in aggravated form. Loose coal is a prolific cause of accidents. If firing tools are carelessly placed one is almost certain to find in the same room, steam hose carelessly thrown down, wheelbarrows left projecting from dark corners, skids or planks behind the doors and scores of other hazards inviting accident.

Many boiler rooms suffer from lack of space. Space from the furnace door to the wall of the room, boiler settings, coal pile or other obstructions should be sufficient to permit the withdrawal of the longest firing tool without hazard or inconvenience. If there is sufficient space beside the boiler, racks for tools should be provided on the boiler setting. Other suitable places may be found in front of the setting, the wall of the room in front of the boiler or the back of the boiler setting. Tool racks must be substantially built. They must prevent the falling of tools and must not be in the way. The practice of allowing the tools to lie on the floor is inexcusable.

Exits

Two or more ways of exit should be provided from boiler rooms. The exits should be plainly marked and illustrated and the exit doors should be hinged to swing outward from the boiler room.

Boiler rooms are often slighted as regards both lighting and ventilation. Coal seems to suggest dirt, darkness, and disorder to the unthinking, but the visitor to this department is often impressed by the painstaking efforts of the grimy firemen in their attempts to secure order and safety.

Light (preferably sunlight, either from skylight or windows) should be provided in sufficient quantity to enable the reading of a newspaper to be carried out in any part of the room.

Elevated Runways

Elevated runways should be strongly constructed and adequately railed and protected. Entrance should be by metal or concrete stairs. Flooring of runways should be of grating type rather than of solid construction—the likelihood of accumulating coal dust on closed runways influencing the choice.

Several levels of runways may be found in the properly equipped and up-to-date boiler room, whereas in the older construction ladders are depended upon to reach the several points necessary in the course of a day's work. In addition to stairs and runways, chain or indirect control of several of the vital valves and safety appliances will be found most advisable.

Flooring

Brick flooring is sometimes recommended in handbooks dealing with subject. While it is a non-conductor of heat it lacks smoothness and does not lend itself to efficient operation.

Types of floors may be different around boiler settings and under coal piles. Floors immediately around boilers should be of metal plate with abrasive surface or of concrete. Under the coal pile, concrete will afford a suitable footing and will not interfere with the use of the shovel.

Storage of Fuel

If coal is dumped from railroad cars into a hopper a metal grating should be used near the top of the hopper to prevent a man falling into it. The grating should be of such a type as to permit of the efficient handling of the coal and at the same time to afford maximum protection to the workman.

A workman entering a bin should wear a safety belt and life line. The upper end of the life line should be attached firmly to some stationary object and a companion workman should keep the line adjusted short enough to prevent the man in the bin from being drawn under material.

Hot Wells

Hot wells should be fenced in or otherwise protected. If the well is less than fifteen feet in diameter the entire surface may be covered with metal plate or grating one foot or more above water level. If the hot well is more than fifteen feet in diameter or grating extending out

six feet or more from the side of the well may be installed with an appreciable slope toward the curb of the well and safety. Closed hot wells should, of course, be provided with a pipe at least ten feet in diameter and of sufficient size to permit of the escape of vapors.

In the economizer the temperature of the water is frequently raised to nearly that of the boiler. As the economizer is under the same pressure as the boiler, precaution should be taken to maintain and operate them with equal care. The water should enter the boiler after passing through a check valve. A safety valve should be provided for each economizer.

Many engineers recommend that the tops of boiler settings be made flat so that repairmen and others are provided with a rapid means of escape from the tops of the boilers in an emergency, and with a safe route to travel in their work. This may be done by filling around the drums or shells with an insulating compound, with four or five inches of concrete on top.

If flat top settings are impracticable a continuous walkway (with standard railings and toeboards) should be provided over each bank of boilers. The walkways should be arranged so that steam valves and safety valves are accessible from them.

Safety valves should not discharge across the tops of boilers. Direct the discharges upward and have them above the heads of workmen who may be working around them. When discharge pipes are carried through the roof they should be at least seven feet above the roof level.

At least one recording gauge should be connected to each steam system so that should an accident occur there will always be available a record of the steam pressure at that time. All steam gauges should be kept in good condition so that the pressure indicated will be approximately correct. For testing gauges a dead weight testing machine should be used.

Each boiler will be equipped, of course, with a water column and fittings. This should be located so that a view of the gauge glass from the boiler room floor is not interrupted by stairways, platforms, etc. Where it is necessary to provide a special platform for the water tender, this platform should not interfere with a view of the gauge glass from a position on the boiler room floor because it may be necessary to verify the water level from this point.

Drain connections from the water column should have an open end into a drain and be of sufficient size to permit any foreign matter that may enter the columns to be blown out. The drain connection should not be led into the ash pit, however; water striking hot coals will form carbon monoxide gas, a deadly gas, also explosive if mixed with air.

Guards are usually desirable where glasses are less than fifteen feet from the floor or water tender's platform. Glasses above this height may be obscured by some kinds of guards. Therefore, nothing is recommended except where men work near the glasses.

There are a number of glasses on the market which employ the principle of refraction to show the water level. These glasses usually have flat fronts and ribbed backs. They show a steel gray color above the water line. Disadvantages are that the water level can be observed from only one position and grease and dust collect in the grooves so that the glass has to be removed and cleaned. This glass is safer than the ordinary unguarded cylindrical glass. Wired glass guards surrounding the gauge glasses are very good where the location of the gauge exposes the workman to danger. They are objectionable when the gauges are some distance from the firemen or are poorly lighted, because glasses cannot easily be seen through them. They should be used on locomotive boilers where glasses are close to firemen.

Enamelled plates with vertical red and white stripes are sometimes placed behind gauge glasses to illuminate them.

All gauge cocks should be arranged to operate from the floor. Instead of having rods or drains attached to them it is often possible to arrange cocks with levers having holes in them so that they may be operated by means of a rod with a hook on the end. When not in use such a rod should hang at a given place conveniently located. Such an arrangement prevents the accidental movement of cocks.

Gauge Glass Breakages

Gauge glasses break from many causes. Brittle and unproperly cooled glasses break easily. Only the best glass should be purchased. Long glasses break easily; glasses not longer than 12 inches should be used.

Ends should be fused when cut as glasses are materially weakened by the broken surfaces. Impurities in the feedwater attack and wear glasses. If glasses wear rapidly experiments should be conducted to find a glass better suited to the water.

Glasses may be worn somewhat by the action of the steam and water passing through them. When the wear becomes perceptible glasses should be renewed.

Glasses should be protected from drafts or sudden chills. Sudden cooling of glasses places great strains upon them and will break any but the very best.

The expansion of the plates and the pressure in the boiler are apt to cause connections to move and break the glasses when they are mounted directly on the heads of boilers especially when mounted on bent plates. Eliminate this by the use of water columns.

Care should be taken to have the connections in perfect alignment and to place glasses in connections so that there is no strain on them.

Gauge glasses are very susceptible to mechanical injury, and if only slightly scratched are easily broken. Exercise great care in storing.

Gauge glasses should be protected from accidental blows. Breakage often occurs when gauge glasses are struck by the elbow or with a tool.

Many glasses are broken by turning the water into them carelessly when they are first put in. After renewing the glass proceed in the following manner:—

1. Replace guard and move as far away as possible.
2. Open gauge glass; blow down.
3. Open steam cock at top of glass slightly.
4. Leave in this position until glass is hot.
5. Close blow-down.
6. Open upper cock wide.
7. Open lower cock wide.

(Open and close all cocks slowly)

OPERATING RULES FOR BOILERS

Starting Fires in Boilers

If a boiler in a battery that is in service has been out of use for a time sufficient to permit all parts of the setting to become cold, or if it is a new boiler, the following method of starting up is advised:—

The stop valve between the "goose-neck" and the header should be tight; the drain pipes in the goose-neck and the drain valve underneath the non-return stop valve should be open; and the connection to the steam gauge should be open and in good condition.

Open the feed valve and fill the boiler gradually until the water level stands between the first and second gauges of the boiler.

Start a very light wood fire in the furnace and have the damper in the stack practically closed. The escape of smoke from the setting will indicate any air leaks, unclosed doors or other defects which are undesirable when the boilers are in service. If any such leaks are observed they should be corrected before going further; in the case of a new boiler or a boiler with new brickwork in the furnace, this preliminary heating should be continued for a day or two if possible before going further.

Continue firing with gradual additions of coal, the damper adjusted to the requirements until all the air is driven from the boiler and steam is escaping from the proper channel.

A period of at least two hours should be occupied in

bringing the steam pressure in the boiler up to the pressure in the header, as stated above; if the boilers are new a much longer time should be taken.

While steam pressure is rising in the boiler the gate valves between the boiler and the steam main should be slowly opened. This leaves the boiler still shut off from the main by the non-return valve. When the pressure on the boiler has reached the required amount the non-return valve will open automatically, placing the boiler in connection with the main steam system.

Before commencing heavy firing, corresponding to the service in the remainder of the battery, lift the lever on the safety valve to see if it is free to act, and observe at the earliest opportunity whether this valve lifts at the allowed pressure of the boiler or under it.

At this time the stop valve in the boiler feed pipe near the feed main of the boiler house should be wide open, also the stop valve between the check valve and the boiler; the feed-controlling valve should be adjusted by the water tender to an opening such as will provide the required water delivery.

Checking Fires

The practice of checking fires by opening fire doors so as to permit an inrush of great quantities of cold air into the boiler setting and to the stack is bad from an economic point of view and subjects the boiler and setting to an undesirably rapid change of temperature. Instead of this it is much better to close the ash doors or other sources of draft supply and if further checking is desired dampers should be closed. Finally if necessary fire doors should be opened gradually.

Blowing Out Boilers

The bottom blow-off should be used at least once every twelve hours, the valves in the blow-off connections being left open for a period of one-half minute or longer depending upon the character of the feed supply. A boiler should not be emptied before the setting has cooled.

Laying Up Boilers

If for any reason a boiler is to be taken out of service for cleaning, etc., the following procedure should be observed:—

(a) Check the dampers and allow the fires to burn out, at which time the non-return valve will be sealed; also close the gate valve in the branch next the header and open the drain pipes in the goose-neck or bend.

(b) Shut the stop valves in the feed pipe.

(c) Rapid cooling sets up undesirable strains in the equipment. Cool as slowly as time available will permit. A small amount of air may be passed through the furnace to assist in the cooling. To do this open the doors and dampers slightly.

(d) After the boiler is cool the blow-off valves may be opened and the boiler drained.

(e) If for any reason the boilers are to be laid up indefinitely the following precautions should be taken to provide for safe conditions when boilers are again put in service:—

Thoroughly drain the drums and tubes and clean them inside and out. Then completely fill the boilers and replace covers which have been removed. This method is not practicable when boilers would freeze. In such cases after cleaning the boilers, dry them thoroughly and place a pan of lime in each drum to absorb moisture. Do not replace manhole covers. Some companies prefer to clean and dry a boiler and then smear the insides of the drums with a heavy crude or fuel oil. This should be put on with a swab, and when putting this on an electric light should be used, not an open torch. Drums and tubes should be left open. Mud drums, headers and tube caps should all be cleaned and similarly coated.

In all places where freezing may occur, care should be taken to drain water from all parts or fittings, or, where these cannot be drained (as in the case of steam gauges) they should be moved and stood in warm places.

The above assumes that the boiler is separated from the main header by two valves, a gate and a non-return. In case this condition does not exist, or if the valves leak, a blind flange must be inserted between the boiler and the header.

Cleaning Boilers

The blow-off valves, stop valve in the connection nearest the header and the stop valve in the feed pipe next to the feed header should all be locked shut and the keys retained in the possession of the man in charge of the subsequent cleaning operations. Place on the handle of all of the above valves a suitable sign such as—MAN INSIDE BOILER; DO NOT TOUCH.

Manhole covers may be then removed and the boiler opened up for cleaning. It should be an invariable rule that the man who enters the boiler for purposes of inspection, and who is in possession of the keys locking the above mentioned valves, must give the final assent for the return of the manhole covers to their places.

Previous to entering the boiler it is advisable to determine whether there is any gas or bad air present by passing a torch or candle inside.

For locking the valves as advised above the following method is suggested—Make a loose cover for the hand-wheel out of sheet steel. This cover is simply a circular box made in halves and hinged at one side, with a hole in the bottom for the valve stem. On the side opposite the hinge an arrangement is made so that the box may be locked shut. This box can be painted bright red with the word "DANGER" in another color. For large steam valves the box may also have a sleeve extension to cover the valve stem, thus preventing the use of a wrench on the stem of the valve.

The cleaning of the setting of coal-fired boilers should not be commenced until all flue dust and other material, also the walls of the settings have been cooled to a temperature where there is no possibility of a man being burned by touching them.

The cleaning of gas-fired boilers will necessitate an additional precaution in the way of testing the chambers by means of a lighted candle or torch to detect the presence of gas or bad air. The gas valve leading to such a boiler should be locked shut and the key retained in the possession of the man in charge of the subsequent cleaning operations. A sign, MAN INSIDE BOILER; DO NOT TOUCH, similar to that placed on the steam feed and blow-off valves is to be placed on this valve also.

Leaks in Steam Pipe Systems and Other Structures Under Pressure

If for any reason, such as blowing out of gaskets, vibration, over-straining of pipes or general deterioration the joints of steam pipes develop objectionable leaks, the application of wrenches to bolts of such joints while under steam pressure should be absolutely prohibited. If such joints are to be repaired it should be done after the pressure has been removed from the particular section where the trouble occurs.

If the tubes of a fire-tube boiler develop leaks at the tube sheet, expanders should not be applied to the ends of the tubes while the boiler is under pressure.

If a leak develops at any part of the sections of a boiler whether in the headers to which the tubes are attached or at a riveted joint, the use of a caulking tool to stop this leak while the structure is under steam pressure should be prohibited. This applies to rivets as well as plates. All such repairs should be made after the steam pressure has been taken off the boiler.

If a leak develops at the hand-hole plate or around the tube caps of water-tube boilers same should not be stopped by tightening up the bolts while steam pressure is on the boiler. The same applies to leaks at manhole covers.

Rising stems of valves should not be permitted to be-

The Economizer in Power Plant Operation--II.

The Following Article Reprinted From a Paper Read Before the Boston Section of the A.S.M.E. Gives Some Valuable Data on Economizer Operation

The Heating of Feed Water

THE heating of feed water is a subject of interest and is having the serious attention of all leading engineers of the present day. With an attainment of the best combustion, an efficient boiler adopted, an economic prime mover, then the study of advanced engineers is to reduce the 20 per cent. or more fuel waste in the boilers and reduce the 20 per cent. of the total steam generated that is now required to operate the auxiliaries.

Now, first, let us consider the auxiliary requirements for a reciprocating engine run condensing, which we will assume is used for belt drive in a factory.

Shall the feed pump be operated by power or steam?

The opinion on this is diverse and the able practitioners consulted seem to be evenly divided.

Those favoring steam-driven pumps seemed to think them more reliable for steady operation with automatic control.

Those favoring power-driven types advanced that a six-plunger power pump provided with an automatic relief valve to bypass, has proved to be reliable and eliminated severe pulsations on the pipe lines.

For relay with power-driven pumps, some would provide injectors, particularly with reference to plants of moderate size; and other steam pumps.

Where steam-driven, all would use the exhaust in a secondary heater for heating feed after the water taken from the hot well or other original source had previously gone thrugh the primary in the exhaust between main engine and condenser.

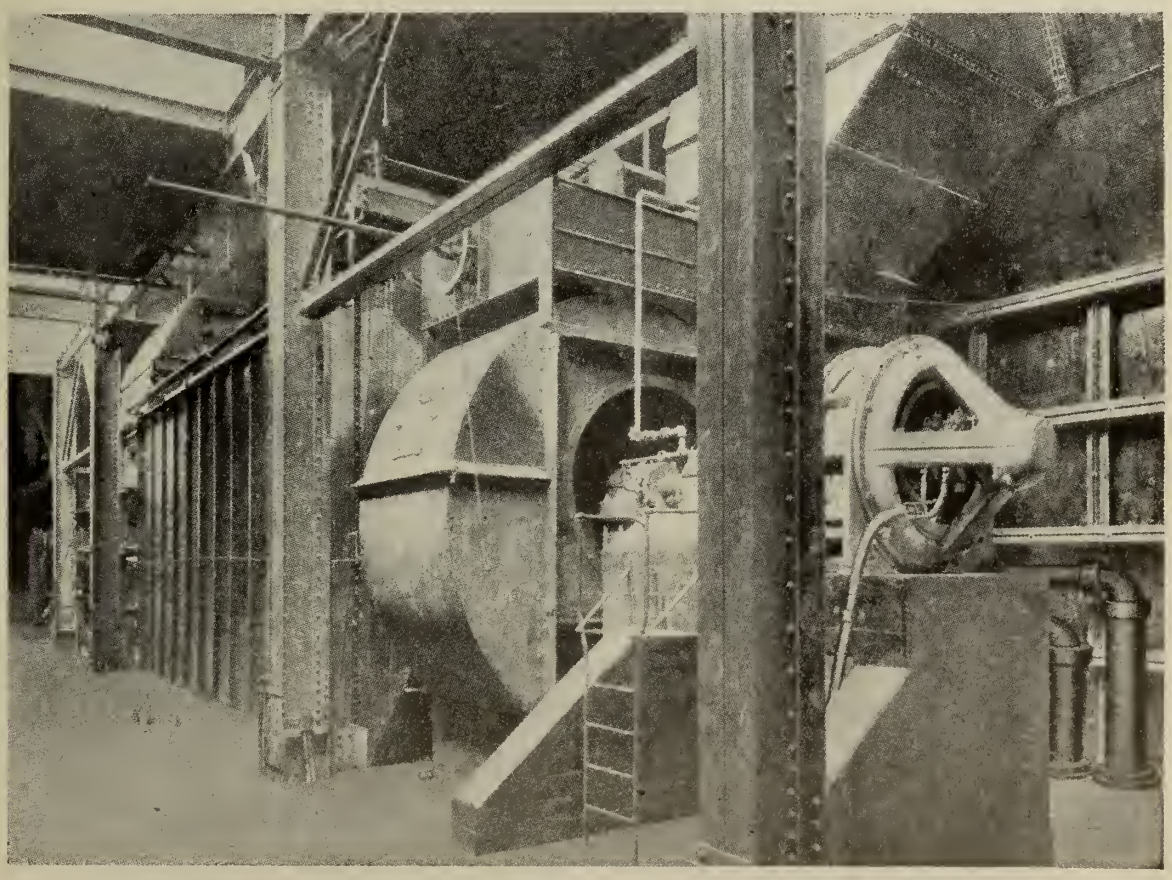
Presuming the condenser pump is not of a barometric type, shall the condenser water be circulated by steam or power pump?

Nearly all prefer this pump to be steam-driven, although they seem to regard the steam consumption to be high and many speak a good word for the economy of the old custom of direct connection to the marine engine, but concede the independent type has operating advantages.

If this steam auxiliary is of an economical Corliss type, it will require only about 3 to 4 per cent. of the steam used in the main engine and this exhaust will add about 30 degrees to feed water temperature, varying more or less, as 20 per cent. more or less of the boiler output on the average is customarily used for heating in an industrial plant and other moderate uses. The reciprocating engine for public service electric stations is not considered, as it is not present-day practice. If a twin vertical, high duty pump is used, about 9½ per cent. of the total steam is used to drive them and the exhaust would add about 80 to 100 degrees to the feed water. A compound pump will use about 6 per cent. of the total steam and the exhaust will correspondingly add between 50 to 60 degrees to feed temperature.

Hence it can be seen that with the 5 per cent. of steam that would be obtained from a steam-driven feed pump added to extravagant types of condenser pumps, an engineer could easily provide a feed water temperature at 200 degrees or better.

The most economical method for operating the auxiliaries would be power-driven feed pumps and Corliss



SIDE VIEW OF ECONOMIZER AT BLACK ROCK PLANT OF THE BUFALLO GENERAL ELECTRIC COMPANY.

condenser pump. The feed water would then leave the primary heater at 110 degrees; the secondary heater at 140 degrees, and from the economizer 240 degrees.

The belted feed pump would take only 8 i.h.p., say, for 1,000 h.p. at, say, 15 lbs. per h.p., or 120 lbs. against steam-driven at, say, 8x150 lbs., 1,200 lbs. steam per hour, or 1,080 lbs. saved by power driven from main engine.

The Corliss pump at 3 per cent. saves 6 per cent. of the total steam over the twin vertical, or one of similar steam consumption, which would have to be used to obtain 200 degrees temperature in feed, or 900 lbs. more saved, making a saving of 2,000 lbs. of steam otherwise to be manufactured. The combined use, therefore, of the belted feed pump and the Corliss condenser pump makes a saving of steam of at least 10 per cent. based on additional moderate amount of steam for heating, etc., used outside of engine and on top of this, the economizer heats the water to 240 degrees, or 40 degrees hotter than 200, giving another 4 per cent. This would make a total of 14 per cent. against running auxiliaries to give exhaust steam sufficient to deliver the water into the boilers at 200 degrees. This scheme, as just recommended, is being followed in many plants. Where plants can use some exhaust continuously in the mill, then more auxiliary waste can be allowed to such purposes, but the highest fuel economy will be had by limiting this supply to what can be thus fully used, and with sufficient to heat the feed temperature to enter economizer between 120 and 140 degrees.

I have been among power plants for over 20 years and every practical operating engineer I have met has always complained of the loss of steam used in small engines and auxiliaries. They know every piece of steam apparatus carries its own losses and if you get 80 per cent. recovery of their steam you are doing well.

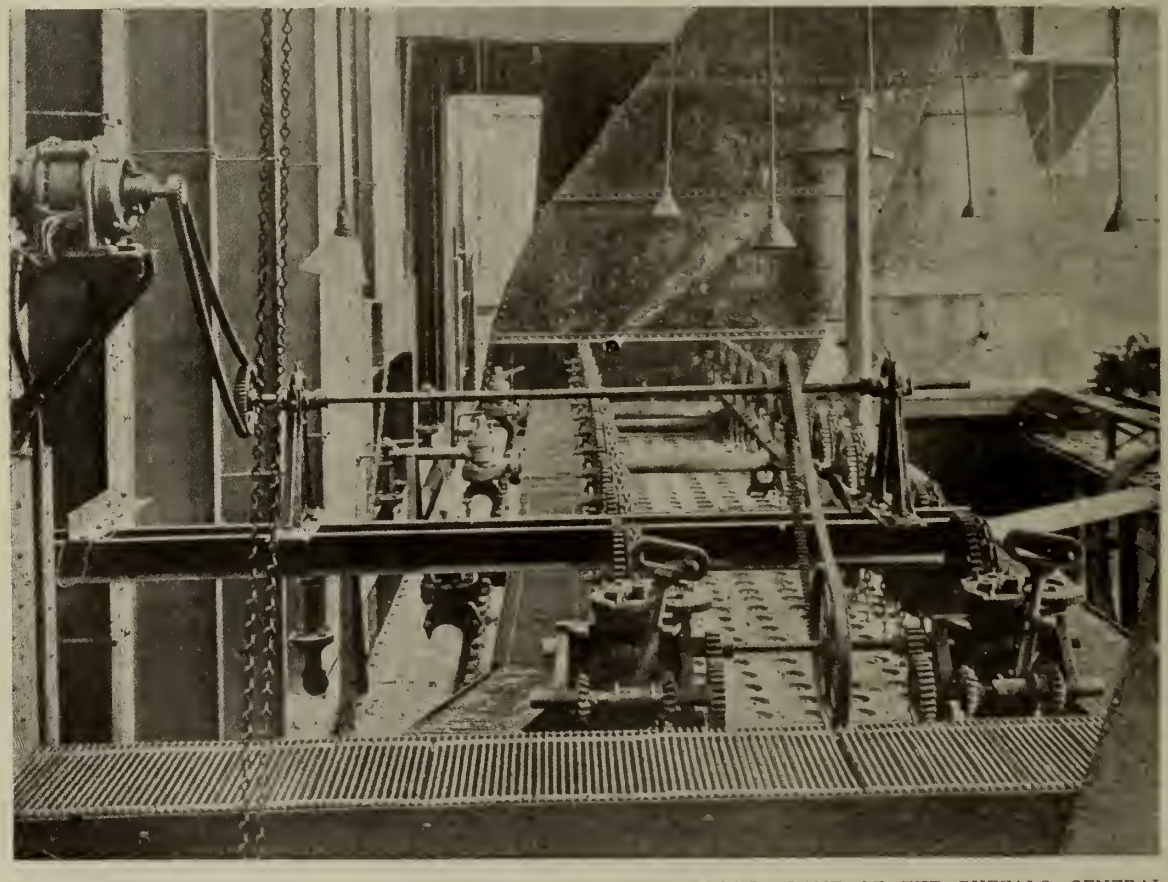
Capt. Manning tells me that it has been the practice in the Navy to heat the feed water by live steam and discharge the exhausts of auxiliaries into the main condenser to lessen the amount these use, and this has been their practice for over 15 years. Surely where every pound of water and fuel has to be carried aboard the ship our expert naval engineers would not be doing this if it were not provedly economical.

My outline for operating auxiliaries and heating the feed water through the feed water heaters and economizer showed a combined total saving of 14 per cent. Practically it will be nearer 16 per cent., because you will get only 20 per cent. recovery of the waste on the other method, and then the saving will be even greater, because the ratio of combustion being reduced in a given boiler unit for a less duty, produces a higher boiler efficiency, and therefore a compound saving is effected. Every conscientious expert who has ever tested economizers has almost invariably found this result true. Then, too, consider that the water is held nearly an hour's time, so many impurities have chance to be precipitated, therefore the water is pure and ready to ebulate.

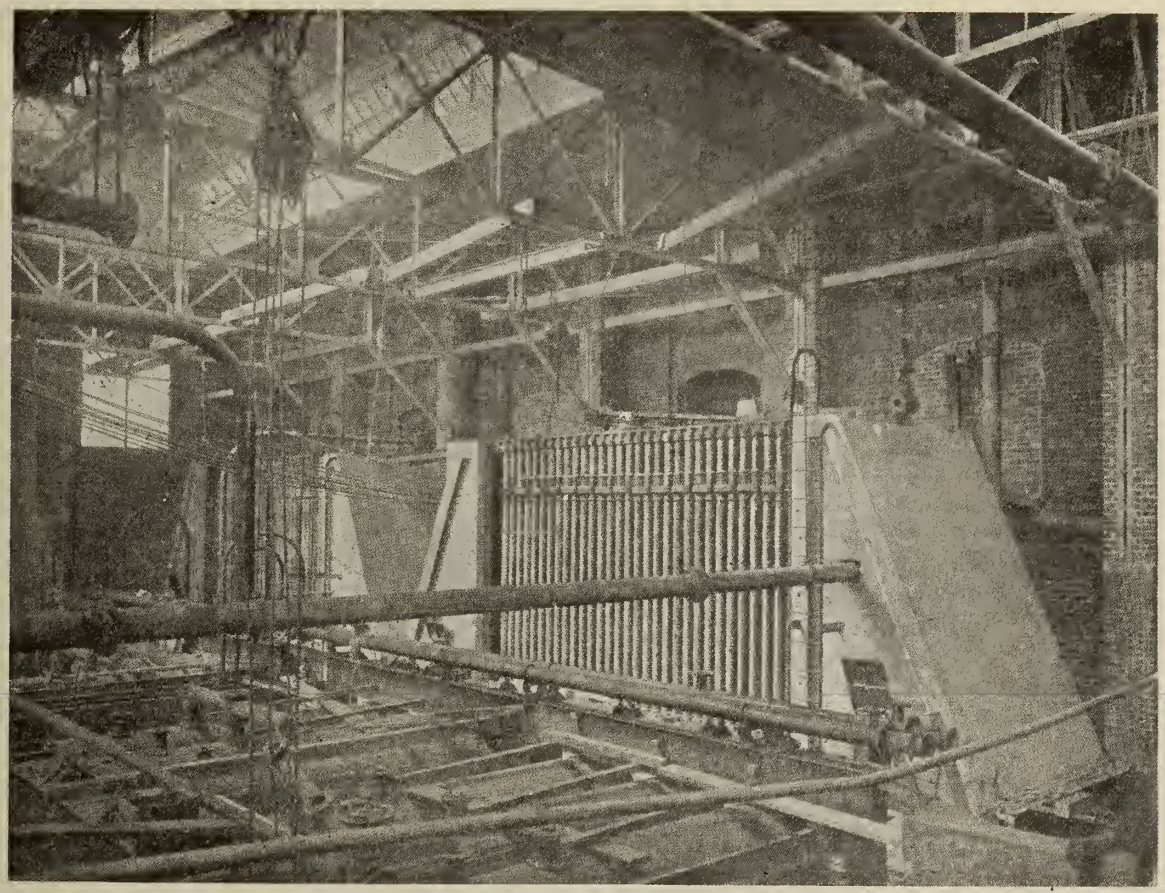
The use of the exhaust in the low pressure cylinder can be granted to produce useful economy. Some object to the method because the steam may be wet, necessitating the complication of reheating coils. Sometimes these coils are utilized to carry the live steam to operate the condenser pump. So while this low pressure duty does seem to work well in practice, and I know of no positive troubles, I gave my former outline the preference, as it looked simpler, was easily understandable and probably as equally effective in net economy. This alternative method supplies steam feed pump exhaust to the secondary heater instead of condenser exhaust, the latter being condensed or used to manufacture power in the engine.

The operation of exhausts from auxiliaries into the main condenser has met with objection that their leaky valves will destroy the vacuum, but I found its adherents, who claimed they had never had such troubles where the vacuum carried was not higher than 26 in.

With a barometric condenser the feed pumps will be steam-driven to provide a source of exhaust to the secondary heater.



TOP OF GREEN'S ECONOMIZER INSTALLATION AT THE BLACK ROCK PLANT OF THE BUFFALO GENERAL ELECTRIC CO. TWELVE ECONOMIZERS INSTALLED, EACH IN CONNECTION WITH ONE 1200 HORSEPOWER B. & W. BOILER OPERATED AT 400 PER CENT. RATING PRESSURE 275 LBS.



GREEN'S ECONOMIZER INSTALLED IN THE PLANT OF THE CALIFORNIA AND HAWAIIAN SUGAR REFINERY CO., CROCKET, CAL. THE CONCRETE FLUES SHOWN ARE AN INTERESTING PIECE OF DESIGN.

It may be asked why the author insists on a secondary heater or in effect to secure 150 degrees for entering economizer temperature. Why not be logical and run every auxiliary by power and save all their wastefulness and just take the water from the primary heater to the economizer? This could be done if someone were to be in charge of the plant to have any apparatus that could be reliably run, operated off the main power.

But in many plants where the boilers have to be fed with water at 110 degrees or thereabouts, it happens when economizer is shut off for repair or cleaning that the coaling is so heavily increased and the labor of keeping steam likewise, as compared with the ease had with economizer, that the engineer is loath to disturb its service—lets minor leaks run in, awaits the favoring time when the plant won't be too busy, and then has other things to do, knowing the rugged economizer can stand a while longer. The thorough cleaning and overhauling of once or twice a year that it should have is not given to it for years.

The same chief auxiliaries of the reciprocating engine of feed and condenser pumps and also another important auxiliary, the Exciter engine, are required in modern turbine stations and some comments on them follow:

The Feed Pumps. In some important plants it will be found that these are run motor-driven with steam relay, although elsewhere, steam-driven by duplex pumps, chosen for reliability, or small turbine-driven centrifugal pumps. A three-plunger power with motor chain drive and steam relay should prove a reliable and economical rig—or what will develop more probably will be centrifugal motor-driven pumps with small steam turbine to automatically relay.

Condenser Pumps. Practice on these is diverse between motor-driven and steam. Where steam driven the exhaust is sometimes led to the condenser, but the higher vacuum of turbines than to reciprocating is apt to generally give more trouble with leaks through valves of these small steam pumps or small turbines. Lately the Terry turbine has brought out a turbine with the steam flow reversed through the low pressure element and thus protecting the valve gland to enable them to run with an economical use of steam by condensing the exhaust.

Mr. William Pestell tells the author that the new turbine going in at the Manchester Station in Providence, R.I., is being planned to turn the exhaust of the condenser pump into the fourth stage of the main turbine. The pressure varies, but is expected to be about 8 lbs. absolute, or equal to 14 in. vacuum at this stage. Although the general use of the exhaust from steam-driven pumps in past years has been to feed water heaters, the present tendency is to find a right method that will reduce the steam these pumps consume.

The Exciter Engine. This has been usually engine-driven, because reliability was better with an engine than motor, as a motor trouble or a falling away of 5 per cent. to 10 per cent. would likely cause a shutdown. The exhaust has been generally used to heating feed water.

Primary heaters are in use in some turbine plants, but there has been so much steam from auxiliaries that they are not of much account, especially to heat of steam going to low vacuum. Except where all auxiliaries are motor-driven, as at Quincy Market, such a heater would be of no account.

It may be worth mentioning here that this plant is the largest cold storage plant in the world, with millions of dollars' worth of perishable stuff held in its vast warehouses, and must be kept going every hour of the year, especially in the summer months, where a short shutdown would mean tremendous loss. In this plant, city water is heated by primary heater to 90 degrees with 29 degrees vacuum on the condenser, and is raised by the economizer to 180 to 210 degrees. The economizer is admittedly 50 per cent. too small, but present space

conditions limit its extension. They also have induced draft. Their management spares no expense to have the most perfect equipment to be procured.

Mr. F. L. Fairbanks, the chief engineer, says he does not feed his city water back into the boilers, because there may be times when the auxiliaries are steam-driven and condensing, so there is a possibility of oil getting into the boiler. While such occasions are rare, only a few hours, perhaps, in the month and could be provided against; he also admits using a very trifling amount of oil in the steam to his turbines. This he does to prevent wear on the blades and accumulation of deposit on the low pressure blades—both effects causing a practical disadvantage to the efficiency and maintenance of the turbine. He therefore believes it pays to eliminate both these factors, as he claims he does, by cautious use in admitting oil and throwing away the condensed steam.

Another item of interest was the information that in one electrical station, where they had more steam from auxiliaries than the feed water heaters could take up and absorb, they changed over the exciter to be driven by a motor with a Terry turbine, on the same shaft and kept turning with the motor, and whenever the motor fell off below 5 per cent. the turbine power would cut in automatically and take up the load.

There may be another serious and important steam waste that can be had for feed water if the plant is operating forced draft. J. M. Whitam, Philadelphia, Pa., the well-known expert, speaking on the advantages and disadvantages of stokers, stated, "Those types requiring forced blast will consume 5 to 10 per cent. of all the steam made." This statement was made some time ago when conditions were not as strenuous as to-day.

A difficulty to precise figures is, that it is well-known with practical operators that the steam for auxiliaries is not appreciably lessened when the load falls off, so their steam consumption is relatively higher on the average than the figures I have employed.

It will be of interest as an example of latest practice to look at the equipment going in the Fisk Street Station of the Chicago Commonwealth Edison Co., of two turbines, one 2,500 kw. English Parsons, and the other a 20,000 kw. General Electric, which will bring the total service capacity of this station up to 165,000 kw.

Boilers

Steam is generated by B. & W. boilers.

Each boiler contains 2,440 sq. ft. superheating surface.

Each boiler contains 12,200 sq. ft. h.s.

Total surface in boiler, 14,640 sq. ft. h.s.

Ratio of economizer to boiler h.s., 70 per cent.

Normal rating per 10 sq. ft. boiler heating surface, 1,220 B.H.P.

If economizer is regarded as extension to boiler h.s., 2,070 B.H.P.

Steam pressure, maximum, 225 lbs.; normal, 210 lbs.

Superheat, 200 to 225 degrees.

Evaporation, 80,000 lbs. actual under continuous working conditions. Approximately, 2,400 B.H.P.

Temperature of feed entering, 280 degrees.

Grates—Two chain grate stokers to each boiler, each 13 feet long by 10 ft. 6 in. wide, or 273 sq. ft. area.

Ratio, B.H.S. to grate area.

Ratio if economizer regarded as add'l B.H.S.

Draft

One steel stack, 259 ft. 6 in. above boiler floor.

Inside diameter, 19 ft. 0 in.

Will serve to 8 boilers.

An induced fan provided to each boiler stated to have 80,000 cu. ft. per minute and designed to maintain 1½ in. draft in up-take of boiler.

Using economizer, 1 cu. ft. gas per minute per 1 lb. water per hour evaporated, I regard as good practice.

I do not know at present the size of those fans, but if they are not too closely designed and constructed to exact duty as above, then they could, no doubt, handle double volume if the grates could handle the coal.

Condensers. Both turbines have Worthington surface condensers, and the circulating centrifugal pumps are each motor-driven—for the larger turbine a Kinetic pump is employed. It is claimed that in tests made on this arrangement, a vacuum of 29.8 in. with barometer of 30 in. was had with water used in the jets of 74 degrees, whereas the temperature corresponding to the vacuum is 36 degrees—the water being actually 38 degrees warmer.

In connection with the Kinetic chamber is a feed water tank with float to regulate the supply in which the water is stated to be heated by steam jets supplied from connection between the high and low pressure cylinders of the turbine, or by the exhaust from the steam-driven feed pumps.

"The installation of boilers and economizer is similar in all respects to that of the 25,000 kw. Parsons unit. The exhaust from the steam auxiliaries is carried to Baragwanath heater, guaranteed to heat the water from 65 degrees to 130 degrees.

The economizers are designed to raise the temperature an additional 150 degrees.

The exciters on both turbine outfits are direct connected on the main turbine shaft. See plan view and photo, page 633. Apparently recent practice has overcome former difficulties to this method and, no doubt, some source of relay current to exciter is provided.

MAKING THE BOILER ROOM A SAFE PLACE TO WORK

Continued from page 488

come rusty or covered with dirt so that they cannot be moved the full extent of their travel at any time. A periodic inspection, not less than once a month, of all valves, stems, etc., in all the main piping systems about the boiler house is recommended. Too much importance cannot be attached to keeping the valves in such condition that they are always ready for use.

Great care should be exercised in using a wrench or bar in opening or closing a valve. The abuse of this means of facilitating the handling of valves may result in damage or accidents to seats, threads, stems, etc.

Steam should always be admitted into empty piping very slowly. If any portion of the piping has remained unused for an hour or more it is important that it be completely drained before steam is again turned into it.

Water columns should be blown out completely at least twice every turn. If a gauge glass is fouled internally so that the water level is not clear, the glass should be cleaned or replaced as soon as possible. If the fouling of the gauge glass occurs frequently it is due to some characteristic of the water such as suspended matter, scale solvents, lubricating oil, etc., for which some remedy should be devised.

Try cocks should be used at least twice every turn which will keep them in good working order.

General

No one should be allowed to remain unnecessarily in a boiler room. Visitors are not only in danger if an accident occurs but are likely to distract the attention of the boiler room employees and cause them to neglect their important duties.

Good ventilation should be provided for basements and subways to boiler rooms. In those places there is grave danger of the accumulation of noxious gases.

Remove or minimize every stumbling hazard in the boiler room. Tools in racks, steam hose in its place, proper drainage of wet places and safe disposal of fuel all will prevent accidents.

Scale in boilers causes bulges and ruptures of boiler shell—usually leading to explosions. Remove the scale frequently.

Power Plant Management—Lubrication--II.

Part Two of an Article Giving Some Interesting Data Relative to Lubrication Problems Encountered in the Power Plant

By ROBERT JUNE, Mechanical Engineer

Principles of Lubrication—Part II

ATTENTION was called in our last discussion to the very great importance attaching to the proper selection of lubricants for the various services about a plant. It was stated that this importance did not lie in the opportunities to effect savings in oil, but savings in power, through reduction of friction losses. Sufficient emphasis can hardly be laid on this point, for discriminating choice of lubricants may result in savings in power sufficient to pay the oil bill several times over each year.

We have already dealt with the general characteristics of a good lubricant, and with chemical tests for determining the presence of impurities and adulterants. It remains to discuss the physical tests of lubricants and the qualities most desirable for various service.

The following are the physical tests of lubricating oils commonly employed:

1. Color, Odor and Specific Gravity: These are of value to the specialist in identifying the sample of oil, but they are of little practical value to the majority of operating engineers, and need not be described.

2. Flash Point: The flash point of an oil is that temperature to which an oil must be treated at a given rate so that enough fluid is freed from its surface to be momentarily ignited when a small flame is applied to it. The Cleveland Open Cup Tester is the instrument commonly used for this purpose. A thermometer is suspended in the oil, which is slowly heated; the test flame is applied at every rise in temperature of 5 deg. Fah., until the flash occurs.

Flash point is determined as a measure of the oil's volatility. With steam cylinder oils, it is of primary importance, the required flash point depending on the temperature of the steam at the engine. In the case of oils for bearings, flash point is important because it indicates the presence of volatile kerosene or naphtha, with accompanying fire risks. Plant blazes are always apt to occur with oils of low volatility if used in bearings, and this possibility should be guarded against, if possible, in the selection of oils.

3. Fire Point: The fire point of an oil is that temperature to which it must be heated at a specified rate so that active combustion will take place, and continue, when the small flame is applied to its surface. Naturally, its temperature is above that of the flash point. It is unually found to range from 30 degrees Fah. to 65 degrees Fah., and in light lubricating oils, to about 40 degrees F. Fire point, like flash point, is of value when oils must be selected for service at high temperatures.

Cold Point: While the term "cold point" is commonly used, it is apt to be misleading, inasmuch as two cold points are commonly determined—first, the cloud point, which indicates the point of separation of the tiny particles of paraffine in oils of that base; second—the pour point, which indicates the lowest temperature at which the oil will run. These two cold tests are of value only where oils must be used under conditions of very low temperature and need not ordinarily be made.

4. Emulsion tests are made in four runs: To 40 cc of oil in each case, is added 40 cc of distilled water for the first run; 40 cc of brine for the second run; 40 cc or normal caustic soda solution for the third run; and 40 cc of boiling distilled water for the fourth run. In each case the mixture is stirred with a paddle at very high speed—say 1,500 revolutions to a minute. The oil should be kept at a temperature of 130 degrees Fah. during the test.

To pass this test satisfactorily, oils used on ice machines or with forced lubrication, should completely separate in less than twenty minutes. The salt water and normal caustic soda solution test need only be made where there is a possibility of water containing boiler compounds getting into the system. The boiling distilled water test is to be made only where there is a possibilty of steam or water at high temperature getting into the oil system. The great importance of this test lies in the fact that where emulsification takes place with any type of forced lubrication, there will follow clogging of oil lines and a formation of solids in the base of the bearings, with consequent large losses of oil and greatly increased friction.

5. Viscosity: Viscosity is the most important physical test of an oil. It may be defined as a measure of fluidity or body. Its value depends upon the internal friction between the particles composing the oil and their resistance to separation. Viscosity is really a measure of rate of flow of an oil at a predetermined temperature, through an orifice of standard size. It follows that the viscosity of an oil is inversely proportional to its fluidity.

Importance of Viscosity Tests as a Guide to Lubrication

All operating engineers have had bearings of machines under their care which increased in temperature when in operation to a certain point and remained at that temperature under normal working conditions. It is not uncommon to find bearings unusually warm and yet causing no worry or anxiety to the engineer in charge, because he knows that these bearings will not heat to any higher temperatures. These conditions are not evidence of satisfactory lubrication, because frictional heat in a bearing is an indication of loss of power, due to excessive frictional load; the power absorbed by friction having been transformed into heat. The causes of the high temperatures in the above described bearings may be credited to the viscosity characteristics of the lubricating oil in use. The viscosity of the oil was too high to give satisfactory results when the bearings were developing normal running heats, and therefore, the bearing was required to develop sufficient heat to reduce the viscosity of the oil to a working value, which allowed it to freely flow into the bearing. With better circulation, the oil was able to balance the production of frictional heat by carrying it away as fast as it was created.

This illustration shows the necessity of using viscosity values, not as a direct guide to the selection of a lubricant, but as an indirect guide. The method of selection of an oil from its viscosity characteristics must be based upon the temperature at which the oil will be expected to work, which in the case of a bearing, will be the normal working temperature of the bearing. At this working temperature, the viscosity of the oil should fulfil the mechanical and lubricating requirements of the bearing.

By plotting the viscosity-temperature curve of an oil, this selection may be simplified and comparisons made quickly with other oils. An example of the practical use of this method is given as follows:

"Assume an engine bearing to have a normal running temperature of 105 deg. Fah. when the engine-room temperature is 85 degrees. In this case, certainly no heat will pass from the air into the bearings. With the exception of the small amount of heat carried away by the engine frame, the 20 degrees excess temperature is a measure of the frictional heat developed in the bearing, and this frictional heat is a measure of wasted energy. If an oil is selected by means of its viscosity curve, produced from the same crude and having the same viscosity at 85 degrees Fah. that the oil in use has at 105 degrees Fah., the friction in the bearing will be reduced, because there will be no necessity for the viscosity of the second oil being reduced to meet the mechanical requirements of the bearings."

It is by far the most efficient practice to use an oil having the lowest viscosity that will insure the maintenance of the lubricating film in a bearing, and excessive viscosity is as much to be avoided as an insufficient supply of oil.

Viscosity of Little Value in Steam Cylinder Lubrication

In the case of steam cylinder lubrica-

tion, the viscosity tests of cylinder oils have very little bearing upon the actual lubricating value of the oil.

It has become the custom of engineers and chemists to compare the viscosities of cylinder oils at a temperature of 212 degrees Fah. (by some at 210 degrees Fah.). A viscosity at this temperature is totally useless as an indication of the lubrication value of the oil, since no cylinder oil is ever called upon to work at this low temperature. Steam at only 75 pounds pressure has a temperature of 320 degrees Fah., while at the usual pressures, the temperatures are much higher, as follows:

125 pounds to the sq. in. 353 deg. Fah.
150 pounds to the sq. in. 366 deg. Fah.
225 pounds to the sq. in. 398 deg. Fah.

It has been found by actual tests that the viscosity of cylinder oils are practically the same at 400 degrees F. and upwards. Therefore, this test is, as stated, of little practical value for cylinder oils, and attention is here called to it simply for the purpose of preventing a loss of time in making it.

6. Friction Tests: These are sometimes made in special testing machines, but the results obtained are of little practical value in widely varying conditions found in actual service.

From what has been said on the subject of physical tests of an oil, it will be seen that service tests must, after all, be the main, though not the only, reliance of the operating engineer; here different oils are tested out under actual working conditions and the lubricant best adapted for the particular service is determined by the process of elimination. There, are, however, certain general characteristics of oils best adapted for particular services and these we will take up briefly.

Steam Cylinder Lubrication: The chief requirements of a lubricant for cylinder oil where superheated steam is used, are high flash point and good body. Since there is practically no moisture with superheated steam, it is recommended that the lubricant be a straight mineral, uncompounded oil of the highest possible viscosity and flash-point. Where steam is not superheated, there is apt to be some condensation on the bottom of the cylinder. In order to aid the emulsification of cylinder oils with the steam, they may be sometimes compounded with "degras" (wool grease). The percentage of tallow allowable for the compounding purposes, is from 3 per cent. for fairly dry saturated steam, to 10 per cent. for low pressure and wet steam and long uncovered lines where the percentage of moisture in the steam will be high.

Cylinder oils should be fed the steam lines at least three fees above the throttle valve, thereby insuring proper and complete atomization. Care should be taken that cylinder oils which have passed out with the exhaust steam and have been received by the hot well, do not enter the boiler with the feed water.

Notes on Bearing Lubrication

Hand Oiling: Hand oiling is very wasteful, as the oil can only be recovered by means of the drip pans. Grit and dirt often give considerable trouble when hand-oiling is used, and close attention necessary to maintain any sort of efficiency from a lubricating standpoint, makes hand-oiling dependent entirely upon the personal efficiency of the operator.

Oils For Circulating Systems: Lubricants used for continuous feed oiling should be strictly neutral, filtered oils. Paraffine, base, or treated oils should be avoided, because of the possibility of emulsification from the frequent churnings, and the possibility of moisture getting into the system, and from other sources.

Gravity Oiling Systems: Combination oil cups and sight-feed needle valves should be used at all points of lubrication. Oil caps should always be kept full and ready for use in case the circulating system fails. In large installations, it is well to take a sample of the oil in use and from time to time take a test as the need for fresh oil can be quickly determined by noting the increased high viscosity. For all gravity feed systems, the point of entry of the oil to any bearings should be at the point of minimum pressure.

Forced Feed Lubrication: Care must be taken not to introduce the oil into the bearings at such points that it will pass through low pressure areas of the oil films, causing counter currents in the films, and escaping without carrying off its proper share of frictional heat. Where plenty of oil is being circulated, probably the best place to introduce the oil is on one of the lower quarters. Lubricants used in all forced feed oiling systems must be neutral, filtered and absolutely non-emulsifying. For the usual turbo-alternator installation, an oil of 150. to 180 Saybolt viscosity at 100 degrees Fah. will give the best results. The oils should have a low-gumming test and be free from al impurities. Treated oils are not satisfactory.

Ball Bearings: The lubricant used in ball bearings must be neither acid nor alkali, but must be neutral. A simple test for ball-bearing lubricants may be made by coating a highly polished steel surface with the oil or grease under observation. After exposing it to the heat of the sun for several days, any corrosive tendencies will be evident upon the polished surface of the plate. Oil containing any compounding of animal or vegetable oils should never be used in ball bearings, as it will produce gumming and become rancid. The best lubricant for these bearings is a strictly mineral oil. For high speed bearings, a light machine oil should be used, and for slower moving bearings, use a heavy viscous oil, or a straight petroleum grease. Petroleum greases have poor viscosities, however, and quickly run out of the bearings. Well-designed bearings are provided with suitable retainers for the purpose of holding the lubricant in the bearing and preventing its creeping out along the shaft. Engine grease or cup grease should not be used in ball bearings, unless it is carefully tested for the presence of free alkali, which will pit and corrode the bearing, if present. Greases should not be used in ball bearings running at over 1,200 R.M.P. Graphite is not satisfactory for use in ball bearings because of its tendency to pack. Oil is the best all-around lubricant for these bearings.

Ball bearings should frequently be flushed out with gasoline to keep them clean.

Roller Bearings: Heavy body oil and medium grease should be used for the roller bearings when the speeds are low; but under normal conditions the speeds are high and will allow the use of machine oil. When oil is used, it should be strictly filtered and neutral, and free from any emulsifying tendencies.

Lubrication of Air Compressors: Air compressor oils must be straight mineral oils and must not be too high in viscosity. They should be examined as to the nature and amount of the residue left after evaporation.

For compression temperatures of 350 degrees Fah. to 44 degrees Fah. the oil should not flash below 500 degrees Fah., and where the temperatures do not exceed 300 degrees Fah. an oil of not lower than 400 degrees Fah. may be used.

When feeding lubricating oil to air-compressor cylinders, care must be taken not to feed an excess of oil, which will result in gumming and carbon-forming deposits.

Refrigerating and Ice Making Machinery

Ammonia Compressor Cylinders: For the lubrication of the ammonia compressor cylinders, a pure mineral oil of good flash test (365 deg. to 400 deg. Fah.) and possessing a cold test of 0 deg. to 5 deg. Fah., should be used. The heat of compression of the ammonia gas requires that the oil have a good flash test, since it must not vaporize too quickly. The possibility of oil leaking, or being carried in vapor form, with the ammonia gases into the condenser pipes and expansion coils, requires that the oil have a good cold test to prevent its solidifying in the piping. A fairly low viscosity oil should be used, one having about 100 viscosity at 100 degrees Fah.

Stuffing Boxes: Hot ammonia gas has a very bad effect on the stuffing box packing of ammonia compression cylinders. A liberal supply of lubricating oil should be applied at this point, to reduce the possibility of overheating the stuffing box.

Lost Capacity: One reason for lost capacity in refrigerating plants is due to the carrying over of the lubricating oil by the ammonia gases, and the depositing of this oil on the interior of the condenser and expansion coils. This trouble is due largely to the common mistake of locating the oil separator entirely too close to the discharge of the compressor. The gases at this point are very hot, and the oil is mostly in vapor form. If the separator is located near the condenser, where the gases have slightly cooled and some of the oil condensed, it is much easier to prevent an

excess of oil being carried into the condenser coils.

Oil Traps: Oil traps, which may be made of a short piece of 3-inch or 4-inch piping, about two feet long, should be located at the lowest places in the expansion and condenser coils.

Measuring Oil Feed: All oil used to lubricate the ammonia compressor cylinders should be measured, and a record kept. If there is any unusual increase in the amount of oil fed into the cylinders, immediate investigation should be made to prevent "filling" of the system.

Oil in Condenser Coils: If lubricating oil has gotten into the condenser coils, it can be loosened by cutting off the water from one stand at a time, and allowing the coil to become hot, when the oil will be thinned and can be run off at the oil trap.

Steam Cylinder Oils: Cylinder oils used in the steam cylinders of refrigerating machinery should be purely mineral, uncompounded oils. A mineral cylinder oil is more easily separated from the exhaust steam than a compounded oil. Either a filtered or unfiltered cylinder oil may be used. Absence of compound is the most important requirement to prevent the formation of an emulsion, with the consequent difficulty of removing this emulsion from the exhaust and condensed steam.

Notes on Lubrication of Textile Machinery

Lubrication of Yarn-making Machinery: For preparatory woollen, worsted, and cotton yarn machinery, such as pickers, cards, combs and all heavy machinery, a heavy engine oil should be used, of 280 to 340 viscosity at 100 deg. Fah.

For Intermediate Machinery: Such as flyer frames, including slubbers, intermediate and roving, a medium viscosity engine oil should be used, of 175 to 200 viscosity, at 100 deg. Fah.

Lubrication of Spindles: It is essential that spindles be lubricated with oils especially prepared for that purpose. These oils must be limpid and free-flowing. They must, however, possess sufficient viscosity to form a protective film of lubricant between the bolster and the spindle.

The oil should have a good evaporative test. When heated for 12 hours at a temperature of 150 degrees Fah. the oil should not lose more than 4 per cent.

The flash test of any oil used in the lubrication of a textile mill should never be below 325 deg. Fah.

Excessive viscosity of spindle oils will tend to greatly increase the friction load of the mill.

The following viscosities are suggested as a guide for the selection of spindle oils for various purposes:

For bath of Rabbeth spindles, doublers, etc., of 95 to 100 viscosity at 100 deg. Fah.

For mule spindles, cup spindles, open bolster, sawyer type spindles, etc., of 140 to 150 viscosity at 100 deg. Fah.

For the general lubrication of ring spinning frames, cap spinning frames, etc., of 140 to 150 viscosity at 100 degrees Fah.

For the lubrication of the front and top rolls of cap spinning frames and for mule frames, of 270 to 280 viscosity at 100 degrees Fah.

A good rule is to oil all the spindles on the frame at noon hour. There are several makes of bolsters. The old type required that the spindle be lifted from from the bolster and the oil poured into it. When the spindle is replaced in this type, the excess oil is squeezed out and usually drips on the frame, and then to the floor. In other makes of bolster, the oil is poured through a tube into an oil cup, making possible the oiling of a great number of frames per day.

"Rail rods" should be oiled every week, when the rails are washed. Oil on the rail rods lasts a long time and they require only a small amount.

The other parts should be oiled at least twice a day.

In mills of any size, amazing results will be produced if a special man, or boy, is detailed to attend to the oiling and wiping of the bearings, with some degree of regularity. It will pay large returns to any mill owner if he will spend some of his time in investigating the lubricating conditions in his mill.

Lubrication of Knitting Mills: For this type of machinery a spindle oil of about 100 to 110 viscosity at 100 degrees Fah. will have the proper body to meet the mechanical conditions of the small running parts. For the general lubrication of circular knitters, a neutral, filter engine oil of 140 to 150 viscosity at 100 degrees Fah. will fill the lubricating requirements.

For the lubrication for the needle motion plates of horizontal knitting machinery, a filtered cylinder oil of 130 to 140 viscosity at 212 degrees Fah. will give the best results.

Highly filtered oils, called stainless oils, are demanded by some mills, under the impression that they will not cause oil spots in the finished pieces. This belief is without foundation, however, as any petroleum oil will "spot" and cause trouble, when the piece is being dyed. Oil spots prevent the dye taking uniformly. Some textile oils are compounded with lard oil to increase their saponification properties, with a view to aiding the removal of spots by washing.

Motors and Dynamos

The same principles govern the selection of an oil for use in the self-oiling bearings of electric machines as is used in the selection of an oil for high-speed engines, having splash-feed bearings. The body of the oil will, of course, vary with the size of the machine. The viscosity should be as low as possible. The oil should have only sufficient viscosity to permit the rings to carry enough of it up to the bearings, to provide ample oil for lubrication and should be sufficiently free-flowing to permit the free delivery of the oil from the rings to the journal. The viscosity of the oil must also be low enough to permit of its free circulation and cooling when it is in the reservoir.

FUEL SITUATION IN CANADA

Use of Coal in Pulverized Form Will Make Available Large Supplies Now Valueless

The fuel situation in Canada is one which must be faced in an effort to overcome the annual threatened shortage and the constantly rising price of coal.

Canada possesses immense coal reserves. Unfortunately, much of it is unsuitable for locomotive purposes, owing to its tendency to spark, also, owing to its high moisture content, it rapidly disintegrates on exposure to the atmosphere. Again, at the mines, both below and above ground, in mining the coal and in handling it, a vast amount of slack is created, which, up to the present, has been considered as waste.

A process for utilizing this slack coal, as well as run-of-mine coal, has for some time been under development. By this method the coal is pulverized until approximately 85 per cent. will pass through a 200-mesh screen and 95 per cent. through a 100-mesh screen. After the coal has been pulverized, it is fed from the bins by screw conveyors and blown into the furnace.

Good results have been secured by cement plants, by the metallurgical industries, and on locomotives. In the heating of large buildings the use of pulverized coal has proved an economical fuel.

The Commission of Conservation, Ottawa, has issued a report on "Pulverized Fuel; Its Use and Possibilities," by W. J. Dick, M.Sc., which explains in detail the use of pulverized coal and its advantages.

ADVERTISERS

POWER HOUSE advertising space is steadily increasing. The splendid list of industrial firms carrying liberal space in POWER HOUSE is an outstanding tribute to the value of POWER HOUSE as a direct-to-the-buyer-and-user of power house equipment in Canada. Our policy of "Power plant efficiency in equipment and service" is meeting with the hearty support of advertisers and readers. Our mutual interests are being acceptably protected and served.

INSTRUCTIVE ADVERTISING

The advertisements of technical papers are usually of an instructive character. Those in POWER HOUSE are exceptionally so, for the reason that POWER HOUSE maintains a policy of co-operation with our advertisers in the preparation of the highest class of advertising information. Engineers thereby become acquainted with the best lines and the merits thereof. We have before us a letter which reads: "We bought . . . . all advertised in POWER HOUSE, and that is what counts, buying right, and it saves a good many hours' hard work." It pays to advertise in POWER HOUSE.

Handy Tools for the Maintenance Man--I.

A Compilation of Various Devices and Methods Used by the Maintenance Man, Facilitating Wiring and Electrical Installations

By JAMES A. PERRY

(Copyright. All rights reserved)

MANUFACTURERS' catalogues contain splendid descriptions of the many regularly-manufactured tools that the electrical worker uses, hence no effort will be made to repeat the description of these. It is, however, the intention to discuss a number of devices that have been found very useful in practical electrical work, and each can, for the most part, be readily made by the electrician from materials always available. Most of the devices are time and money savers.

First of all, any mechanic should have a convenient serviceable chest in which to store his tools. That shown in Fig. 1 has given excellent service in a number of cases. Its construction is sturdy enough that it will successfully withstand the hard knocks to which an electrician's chest is subjected. The design shown was, we believe, first introduced by C. C. Payton, of the Republic Iron & Steel Company, Sayreton, Ala. The heavy tools are placed in the bottom of the chest, while the lighter ones are carried in two trays. One of these trays is attached to the cover of the chest by a series of strap-iron links. The arrangement, obvious from Fig. 1, is such that when the cover is open, this tray, A, is drawn up with the cover. The other tray, B, slides in the usual way on 1 in. x 1 in. guides, while two ½-in. strings maintain it in alignment. When the top is open, both trays, A and B, and the tools in the bottom of the chest are at once accessible.

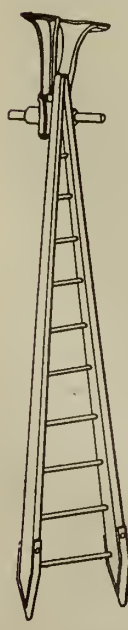

FIG. 2—A LADDER FOR THE INDUSTRIAL PLANT MOTOR TENDER.

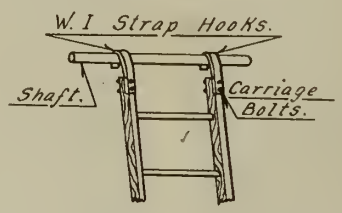

FIG. 3—HOOKS FOR MOTOR TENDER AND WIREMAN'S LADDER.

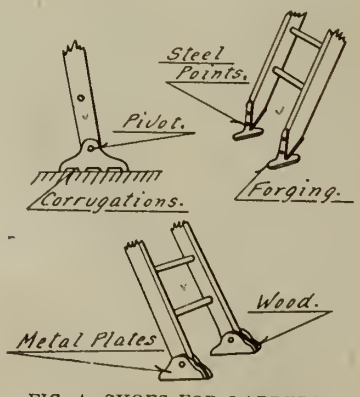

FIG. 4—SHOES FOR LADDERS.

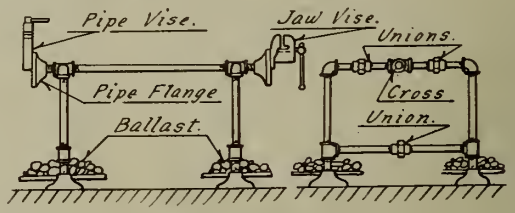

FIG. 5—A KNOCK DOWN PIPE BENCH.

To prevent loss, all tools should be marked with the owner's initials. The marking should be such that it cannot be readily obliterated. A permanent mark can be made on steel tools by the following process with materials that are nearly always at hand: First, the surface of the metal to be marked is covered with a thin coat of paraffine, or drippings from a tallow candle, painted on hot with a brush or rubbed on with the end of a stick. If paraffine or candle is not available, a coating of soap can be substituted. The soap is transferred to the surface by rubbing the end of a cake against it. With some tool that has a flat point somewhat like a screw-driver, except that it should be only 1/16 in. wide, the owner's initials are graved through the soap or paraffine, cutting down to the surface of the metal. Now the etching solution can be applied with a small stick of wood. The etching solution is made as follows:—One part of table salt (by bulk) is mixed with approximately two parts of powdered copper sulphate, or blue vitriol, and the two are dissolved in about ¼ in. of water in the bottom of an ordinary tumbler. After the solution has been applied it will etch the design in the metal to a sufficient depth in a few minutes. Then the tool can be washed to remove all traces of the solution, and the paraffine or soap.

Wiremen should provide themselves with safe ladders. Many designs are in use that afford the safety required. Only a few of these designs which have been given a thorough try-out will be described. The one shown in Fig. 2 is particularly useful around shafting, although it is also handy for work in the neighborhood of steel columns, and where the ladder must be leaned against the stiles or rails of a window. As the illustration indicates, the narrow top permits the ladder to be firmly sustained by a shaft hanger, or similar member upon which it would be difficult to support a ladder of the ordinary type. The lower ends of the two rails of the ladder are shod with strap-iron bindings which have pointed ends. This will prevent slipping on wood floors.

Where the ladder is to be used on concrete or metal floors, a shoe of one of the types suggested in Fig. 4 should be used. That at Fig. 4 A is supported on a pivot, and has a corrugated bottom, hence the shoe always lies normal to the floor. A shoe having pointed spikes extending from its bottom is shown in Fig. 4 B. This type is used where the floors are of wood. A shoe with a wood centre which will provide considerable friction, and hence tend to prevent slipping even on concrete or iron, is shown at C. Where wood—bass wood is the best—does not give sufficient friction, the centre member of the shoe shown at C can be coated with carborundum or lead, which will greatly increase its adhesiveness. Where lad-

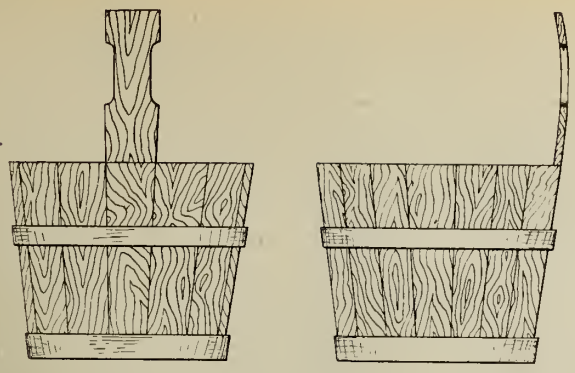

FIG. 6—CARRIER FOR MISCELLANEOUS SUPPLIES.

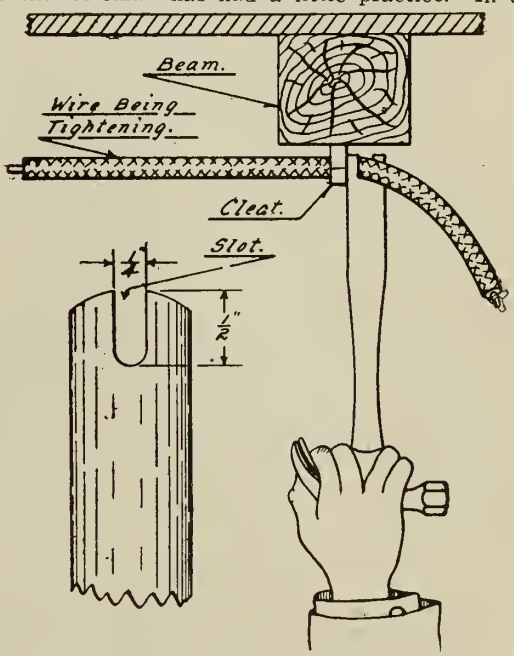
ders without narrow tops are in stock and must be used around shafting, strap iron hangers should be bolted to their upper ends as outlined in Fig. 3.

A portable bench for the conduit wireman is shown in Fig. 5. This device has been particularly useful where the bench has for some reason or other to be dismantled for transportation. It can be readily knocked down and shipped by rail in a relatively small chest at materially less cost than an un-knocked-down bench can be transported. Benches of essentially this same style have been used by pipe fitters in the Western States where it was necessary to transport the tools on pack animals. To knock down the bench, the unions, of which there are six, are unscrewed. Pipe flanges are mounted at both ends for the supporting of the conduit vises. Boards, if they are available, can be laid across the pipes at the top of the bench. They can also be laid across the bottom pipes to form a shelf. The plates are laid with heavy material of some sort to prevent the bench from rocking while pipe is being threaded. Where boards are placed across the lower pipes the load can be put on these instead of on the plates. It will be noted that every portion of the bench proper is of metal, making it very durable.

A useful little kit for carrying around small tools and fittings, such as cleats, bushings, rosettes, locknuts, and washers, can be made from a 100-lb. nail keg, as shown in Fig. 6. The keg is sawed in two at the middle, except that one stave, in which notches are cut for a handle, is allowed to extend. Some wiremen use half a dozen or so of these carriers on every big job, using each one for some different class of material.

A wireman should never erect wire in an open-work installation until all of the kinks or bends have been taken out of it. These bends can, of course, be eliminated if sufficient tension is put on the wire after it is up, but it is much easier and cheaper to straighten the wire before it is placed in the cleats. One good method of straightening wire is shown in Fig. 7. One end of the wire is attached to a nail driven in some stationary substantial object. A knob is run over the wire and then held at an angle and drawn the entire length of the conductor as indicated in the illustration. It is necessary to maintain some tension on the wire while the knob is being drawn along it. This method is best used for No. 14 or No. 12 wires, and may not be successful with larger ones.

There is probably no tool that an electrical worker uses more frequently than he does his pocket knife. If he has its blades ground as shown in Fig. 8, a great deal of time and worry will be saved. One of the smaller blades can be ground on an emery wheel as shown at A. The end is formed to a screw-driver point, of suitable size for socket and rosette work. Near the bolster a notch is cut in the blade. With this notch, fixture wire can be "skinned" very rapidly and without breaking it, after the wireman has had a little practice. In use, the



FIGS. 10 and 11—APPLICATION OF A SLOTTED HANDLE.

end of the wire is placed in the notch and the knife pulled along the wire. The insulation will soon come off.

The large knife-blade that is used almost exclusively for "skinning" wire can be ground as shown at B. As all wiremen know, it is impossible to keep a blade sharp if it is used for scraping insulation, and also for cutting it off. With the grinding suggested, the lower edge can be kept quite sharp, and used only for cutting the covering, while the concave ground upper surface, which provides two edges, is used for scraping or brightening the wire,

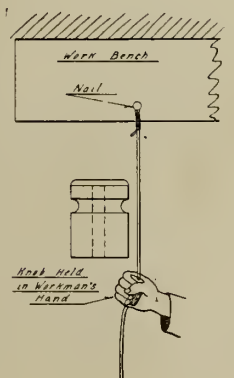


FIG. 7—STRAIGHTENING WIRE WITH A KNOB.

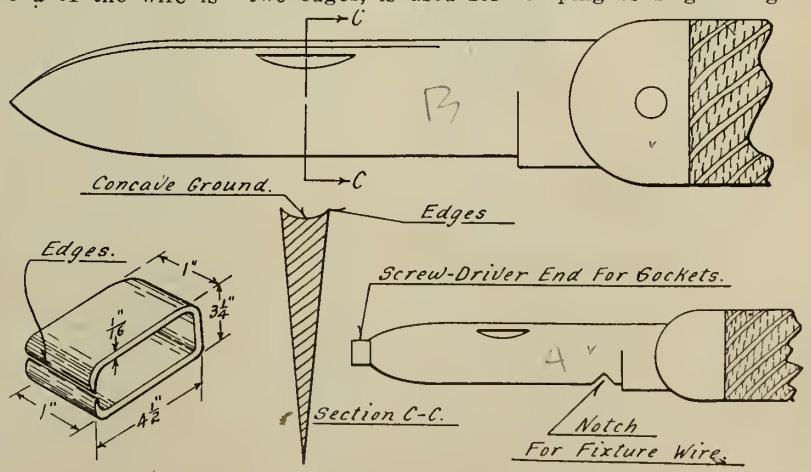

FIG. 8 AND 9—METHODS OF GRINDING KNIFE BLADES AND TOOL FOR SKINNING WIRE.

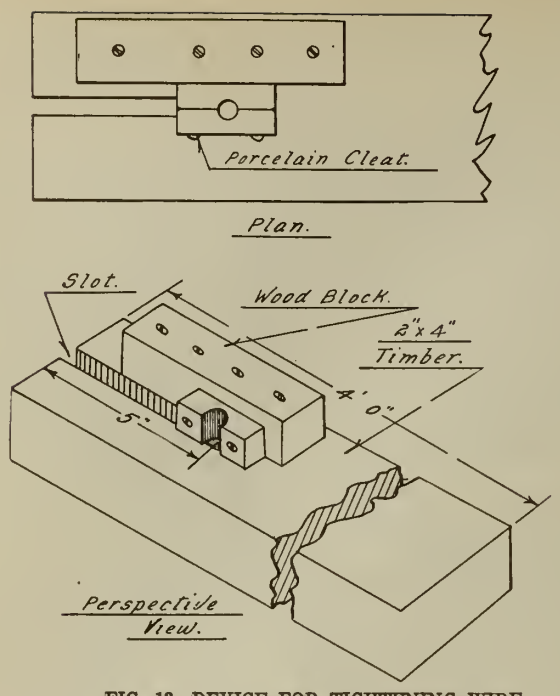

FIG. 12—DEVICE FOR TIGHTENING WIRE.

after the insulation has been removed. The concave edges are formed by cutting a groove along the top of the blade with an emery wheel. The edge of an electrician's knife will usually ultimately assume a curved contour as shown in Fig. 8 B, due to constant sharpening. It will be found that if the knife blade that is used for cutting insulation is ground out rounding, as shown at B, as soon as the knife is obtained, it will tend to prevent the blade from slipping off the wire.

A little tool, very useful for "skinning" lamp cord, can be made as shown in Fig. 9. In use, the lamp cord is held between the two edges, twisted around therein to cut the insulation around its entire circumference, and then the tool is pulled. The insulation—both the braid and the rubber—will come with it, and the strands will not be broken if the wireman uses just the right amount of pressure on the tool. It can be formed from a strip of steel or iron plate. The edges are made with a file.

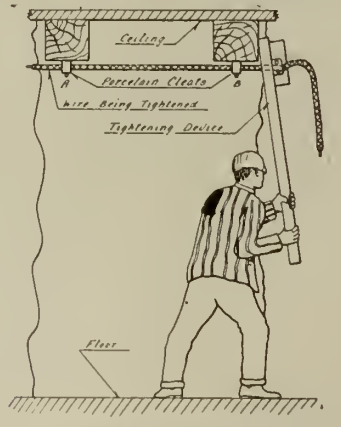

FIG. 13—APPLICATION OF WIRE TIGHTENING DEVICE.

Nos. 12 and 14 wire, in cleat work, can be tightened very nicely by the device shown in Figs. 10 and 11. A slot, ½ in. deep and ¼ in. wide, is cut in the end of the hammer handle, at right angles to the head. The slot being cut, the handle is used as shown in Fig. 10. All wires should be straightened as suggested in a preceding paragraph. After they are partially erected, the sag in them can be pulled out with the hammer handle.

The operation of tightening is as follows:—The conductor is fastened by clamping in one of the cleats at the far end of the run. Then at the near end of the run a cleat is installed, and the wire placed in it. The screws are set up only far enough so as to bind the wire after it is pulled through, and to prevent it from slipping back. Then the end of the wire is inserted in the slot of the handle, and the hammer is turned toward the centre of the cleat. The slack being drawn out, the cleat can be fastened with a screw-driver. After the wire has been drawn taut, intermediate cleats can be installed. It will be noted that this procedure eliminates the necessity of lining up the intermediate cleats by measurement.

Where wires heavier than No. 12 or No. 14 are being installed in cleats a tightening device, arranged somewhat as shown in Figs. 12 and 13, will be useful. Aside from the fact that it is a time saver, this arrangement has the advantage that the conductors can be pulled very taut without the damage to insulation which usually occurs when an endeavor is made to tighten conductors with pliers. The device comprises (Fig. 12) a 2-in. x 4-in. lever, about 4 ft. long, with a slot cut in its end. Adjacent to, and parallel with, the slot a block, possibly 5 in. long and

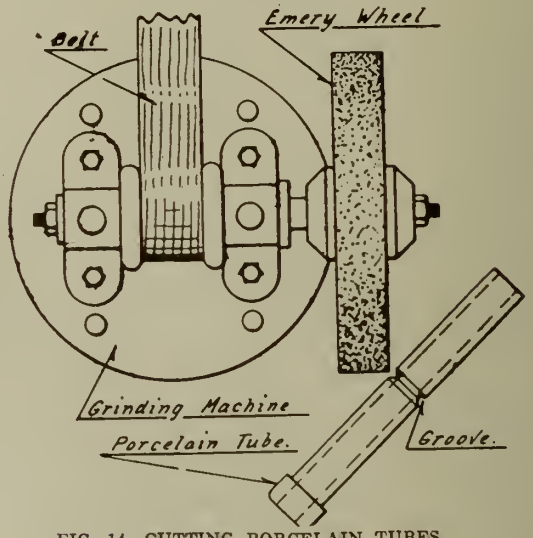

FIG. 14—CUTTING PORCELAIN TUBES.

2 in. square, is fastened with flat-headed wood screws. A cleat is screwed to this block as shown. This cleat may be either of porcelain, similar to those being used on the job, or preferably it can be cut out of wood (maple) or hard fibre. The wire hole in the cleat should lie directly over the end of the slot.

In using the lever, its upper end is placed against a beam or some other member of the building that can be used as a fulcrum, and the conductor is firmly clamped in the cleat. Pressure on the lever tightens the conductor.

A great deal of time is wasted by men that do not know how, in cutting flexible tubing. A majority of wiremen appear to use a knife. Probably the best method of cutting this material, except possibly the very large sizes, is with the pliers. The smaller sizes can be nipped asunder with the large side-cutting pliers almost as readily as can wire. The tubing is thereby flattened, but it can be readily reformed to its normal shape with the fingers.

Large porcelain tubes are difficult to cut without cracking. They can, however, be cut, if an emery wheel is available, by grinding a circumferential groove as shown in Fig. 14. After the groove has been cut, the tube will readily break around it, if it is held by the two hands and subjected to a bending force. After it is in two, the rough edges at the ends of the tube can be rounded off on the side surface of the abrasive wheel. It is easy enough by using this method to cut a large tube in two in 60 seconds, more or less.

To be continued

The Education of the Power Plant Engineer

In the Following Paper Read Before the N.A.S.E. at Springfield This Summer the Author Makes Some Very Interesting Observations Regarding the Status of the Engineer and His Training

By EDWARD H. KEARNEY

THERE is perhaps no trade or profession which is more misunderstood than that of the steam engineer. There is a popular misconception upon the part of the layman that a stationary engineer is a man who "runs an engine." He is to some minds a denizen of remote corners in dark alleys or "down in the engine room" in an isolated section of building where the engine is tethered to a brick foundation and where he plies his trade groomed in an unlaundered blue denim suit. To complete the mental picture of the unsophisticated he is permitted to carry a monkey wrench, a handful of soiled cotton waste and an oil can, as further insignia of his occupation. A graphic portrayal of an engineer either in action or repose would under these conditions show a man not endowed by nature with either striking intellectuality or even ordinary physical comeliness.

To this uninformed instalment of the human race the stationary engineer in addition to his admitted ability to "run an engine" is a "fixer." He is an emergency man, think they, who can and must fit himself into a wide variety of tinkering jobs; if the plumbing fixtures decide to become cantankerous why the first word on everybody's lips is "call the engineer." If the typewriting machine displays a disposition to take a day off it's ten to one that some bright mind suggests instanter that the engineer be appealed to for the concoction of a prescription which will suit the case. If the sewing machine, washing machine or flying machine display symptoms of non-inertia the man who is handy man first and in their opinion "runs an engine" as a secondary consideration is featured as the first choice to inject vim into the flagging patient.

It is exceedingly humorous at times to note in the advertising columns of the daily press the tendency to award a superiority of physical prowess to the members of the steam engineering fraternity. For instance, in one of our metropolitan dailies a few days ago there appeared an advertisement which in substance read something like this: "Wanted, an engineer with second class Massachusetts license. Must be used to hard work and not weigh less than 195 lbs. Part of his duties to be performed after regular working hours." Outside of the fact that the grade of license mentioned carried with it certain scientific qualifications, it would require deep investigation upon the part of applicants for the position or job, whichever might be the correct interpretation, to decide as to whether or not the "ad" mentioned had not been intended for insertion in a sporting paper devoted to athletics instead of a current daily. The specifications for physique certainly would lead one to think that cerebral gray matter was not a consideration worth mentioning. Hard work and long hours appeared as headliners in the advertisement; whether an interval at midday would be allowed for lunch was problematical; perhaps this sparring partner or White Hope, this erstwhile physical marvel when secured would be outfitted with a canteen and knapsack and take a bite as opportunity afforded while not enacting the part of Hercules, Sandow or some other with caveman characteristics.

The above is mentioned in substantiation of the fact that the ability and responsibility of the steam engineer as a class is capable of being misunderstood and the party responsible for the insertion of such an advertisement can be forgiven if the fault lay in his not being far removed in years from the adolescent stage or his experience in the engineering field being confined closely to his own back yard.

Another incident may be related differing somewhat as to scenario and illuminating in the sense that it strikes home forcibly the thought that on this occasion at least one man's mind was disillusioned as to the real status of the stationary engineer. At a gathering of stationary engineers held in recent years a local reporter called up previous to the opening session and requested that he be put in a position to secure some notes for copy in the following morning's issue of his paper. When he presented himself he was ushered into the suite of the president of the organization and in the conversation which ensued he expressed surprise that there were in existence organizations of stationary engineers which went to such great pains in making provision for the technical training and general welfare of their members. He frankly confessed that he had wholly under-rated steam engineers as a class, that his conception of a stationary engineer was not that of a highly trained individual, a man of great versatility, but that his chief stock in trade lay in his ability to "run an engine" coupled with such other unconventional tasks as stoking coal and acting the part of general factotum, with the omnipresent monkey wrench and lubricant container. As opportunity afforded he was introduced to some of the delegates at the meeting and was surprised to learn that almost without exception they were men who held positions of great responsibility, although not altogether removed from the atmosphere of engine room surroundings. So great was the disillusionment of this particular scribe that instead of the "few notes" which he was to accord to the meeting the following morning's edition contained a half page write-up in the news columns together with an editorial which treated of "The Importance of the Steam Engineer in the Community." For a new light had dawned upon him—his vision of the ever-present overalls, grease spots and all the other accompaniments which his mind had conjured up had disappeared and he had deeply imprinted upon his mind the lesson that "running an engine" is but one small detail in the average engineer's daily routine.

A few months ago there appeared in one of our city dailies a news item which must have brought a broad smile to the faces of some of the steam engineers in that section. It appears that the engineers in the water department had requested the city government to increase their salaries some few hundred dollars per year. It was in the natural course of events a matter for consideration by the Common Council and the majority of this board concluded that the granting of the increase in salary was advisable, taking into consideration the importance of the work in which the men were engaged. One of the councillors, however, raised strenuous objection and based his protests upon the fact that such action would breed discontent in the other city departments where "similar unskilled men" were employed. His pin-point intellect evidently failed to connect with the fact that a million dollar pumping plant upon which a city's population depended for service is not under ordinary conditions left to the supervision of or operated by "similar unskilled men." He was perhaps entitled to sympathy for the inconsistency of his comparison; the humor of the situation perhaps never appealed to him.

In the advertising pages of the engineering press we are at times confronted with sketches of an uncouth, frowsly-haired, wrinkled-visaged personage who has evidently been called to the manager's office, and as we behold his abject demeanor and penitential poise we are curious as to whether some great crime has been committed by him and for which infraction of the law summary and condign punishment is about to be administered. One would imagine that the one suit, universally ill-fitting overalls and a peaked cap of ancient ancestry, were the only togs of which his wardrobe boasted—that this unit of apparel answered for work, recreation and social occasions—that in it were combined all the essential adjuncts for use in waking

and sleeping hours. In his attitude as pictured we can almost hearken to the tattoo beaten by the vibration of his knees, the high pitched blows inflicted by his heart upon his ribs, and his tongue so swollen by fright as to render articulation impossible. And all this for what? Is it necessary in order to render conspicuous a supposedly meritorious feature in a power plant specialty to portray such a gloomy picture? The chances are ten to one that the engineer at Squaredeal's mill and that of other industrial enterprises wears a good business suit to work—looks the manager straight in the eye—and knows his end of the game better than the manager professes to—wears shoes not down at the heels at all—caps his think tower in jaunty fashion with the hatter's latest production, wears silk pajamas at night, owns or rents a comfortable home—is well educated himself, and is seeing to it that his children are similarly provided for—and perhaps drives a 50-h.p. gas bus into the bargain.

Happily this form of attracting attention to certain specialties is becoming obsolete and when it has become altogether extinct a glaring cause of misconception will have been removed.

The Realities

But let us leave misconception and turn to realities. What is the real status of the engineer and where may we see the fruit of his work? In almost any corner of the civilized world, whether in city or country, can be seen visible signs of the engineer's participation, and so broad is his field of endeavor that it would be hard to escape from coming into touch with some project in which he was not a direct participant. For instance, without leaving our tracks we see electric lights burning. To the uninitiated the production of this light means little beyond the fact that they see the electric light bulb and knew that by pressing a button or pulling a switch this light is turned off or on. To us as engineers we visualize the whole process of the generation and distribution of the electric current. We know that somewhere in this vicinity there is a power station; in our mind's eye we see a large building topped by a smokestack of considerable girth and height. Our mind then turns to the boiler-room and we know that there are located the boilers where steam is generated. Our mental panorama shows the machines at work which automatically stoke the coal as it is fed from the hoppers overhead. We note the incandescent fuel bed in the furnaces and can sense the heat thrown off. If the capacity of the boilers is mentioned to us, at once we conjure a mental picture of the space occupied by them and the form which they take in keeping with their design; we see huge steam mains and water mains; we know that it takes a large volume of water for boiler feed supply and a very generous supply for the condensing apparatus. Our trained mind instinctively follows in imagination the steam mains from the boiler-room to the turbine or engine room. Here we have a mental moving picture of the prime movers in operation and the immense electric generators to which they are rigidly coupled. We see the condensers and circulating pumps; also the pumps for feeding water to the boilers. We make a mental note of whether they are of the centrifugal or reciprocating type. We, as trained engineers, have mirrored before our gaze the vision of the switchboard with its bus-bars, cut-outs, lightning arresters, circuit breakers, condensers, transformers, voltmeters, ammeters, synchronizers, output meters, line fuses, switches, ground detectors and the dozens of other apparatus all so necessary in electric light generation and transmission.

Education of Power Plant Engineer

But these are only the high spots which we have mentally come in touch with as yet. We as engineers would want to know whether the station turned out alternating or direct current, the voltages carried on the lines; we would desire first hand information as to the design of the turbines and engines, whether Curtis, Parsons, Westinghouse or other design of turbines, or Rice and Sargent or Harris-Corliss or the old plain George H. Corliss engine—and we would like a flash know just what they looked like both inside and out. We might be so curious as to know what the load factor might be. The layman who gazes at these beautiful clusters of lights and lets it go at that might be heard to exclaim, "My, but there is a lot to it, isn't there? I never thought the engineer had to know so many things before." But this list of the apparatus utilized is as yet incomplete in that nothing has as yet been said regarding flow meters for steam and water, air compressors, safety stops, speed governors, indicators, planimeters, insulators, stoker engines, forced draft apparatus, pyrometers, hydrometers, gas analyzers for flue gas, vacuum pumps, draft recorders, coal weighers, coal testing apparatus, boiler feed regulators, reducing valves, pressure regulators, automatic stop valves, boiler cleaning devices, pressure recorders, and so on, almost *ad infinitum.*

The lay mind which sees the effect only and is uninitiated as to the cause would soon become bewildered in an attempt at description, much as if a medical man portrayed to his patient, wholly unlettered in *Materia medica*, the Latin name of an obscure disease, the ancient language method of treatment and the prescription most favored as the panacea for its cure.

Yes, the engineer must know these things. His position requires, too, that he must not only be on the outside looking in, but he must also be on the inside looking out. It would be of little use for the engineer to know how to "start and stop the engine," for machinery, like the human, has its days when it shows a disposition to stray from the path of rectitude. It is prone to have its days off and under these circumstances requires a guiding hand to restrain it from running amuck.

Information of little value could be obtained from a flue gas analyzer, a CO_2 recorder no matter how elaborate its setting if it was considered only as a thing of beauty perched like a piece of bric-a-brac or a treasured family heirloom on a conspicuous pedestal in the front parlor. To secure from it the information it is intended to impart it must be skilfully adjusted and operated. This is the secret of its proper functioning. Otherwise the results secured from it are of negative value. The engineer must be familiar with its mechanical construction as well as its operation in order that it may do its checking with top-notch accuracy. This line of logic applies to every piece of apparatus down to the most trivial accessory in the power plant. The engineer must by training be the doctor acquainted with the inner anatomy of the machinery and apparatus confided to his care. He must not only be able to "run the engine," he must in the mariner's parlance know it "from keel to truck." "Ah," says the layman, "now I begin to see why the stationary engineer is such a studious, sober-minded individual." But wait awhile; we have touched upon his knowledge of things mechanical, but not a word as yet as to his business efficiency.

Engineering as a Business

When a man engages in business and makes a success of his enterprise, we say that he is a good business man. He is conducting his business at a profit. He is turning over his wares at the best possible financial advantage to himself. Does the average layman ever pause to consider what the power plant represents in a business sense? He visualizes in the majority of instances that a steam plant consists of a conglomeration of machinery, a place where coal is fed to boiler furnaces, where boilers are used to generate steam pressure, where engines are running to produce power,—all this accompanied by heat akin to the fire room and the rattle and rumble of machinery in the engine room. How seldom does he associate power plant operation with being conducted upon the same basis as any other well-balanced business undertaking. Does he always look at the coal pile as made up of so many treasury notes? The coal fed to the boilers as representing glittering gold dollars? The fuel burned as money spent and from which a profit must be forthcoming? In other words, does he fully understand what efficiency—a term sometimes correctly, ofttimes haphazardly applied—really means in its relation to power plant operation? But no matter what the popular conception may be, the concrete application of efficiency as applied to the power plant means just this: that those closely identified with the steam plant must be business men just as surely as the dry goods merchandise man is a

man of affairs, or the wholesale grocer conducting business on an elaborate scale.

For power production is business—hardpan, down-to-bras-tack business Put on one side of the ledger the cost of site or rental of space occupied, cost of building and machinery installed, including boilers, depreciation which begins almost immediately after installation, insurance, taxes, repairs, salaries, miscellaneous supplies, and last but not least the money spent in bringing to the furnace door the black diamond—coal. Add these and the other smaller outlays and subtract from the total income derived from the enterprise. The balance, whether favorable or unfavorable, is the same financial problem that must be faced by those conducting any other form of business. Figures, they say, cannot lie; the issue permits of no dodging.

We took for illustration a simple electric bulb, the light from which showed the participation of the engineer in the production of one of the things which almost universally has grown to be looked upon as one of life's necessities. To us as engineers these are some of the thoughts which instinctively flash before our minds and yet only one small detail of power production has been touched upon. We could with equal consistency enter into the problems of the street railway power plant engineer, the refrigeration engineer engaged in the cooling processes in our artificial ice plants, cold storage warehouses and confectionery factories, the office building engineer interested in providing comforts and conveniences, such as electric lighting, elevator service, vacuum cleaning, iced and filtered drinking water, ventilating, heating, and other process work, the mill engineer brought to the front so prominently for the fidelity and patriotism displayed in his almost superhuman efforts to produce material for wearing apparel during the war period, the water works engineer and the hotel engineer each with his ever varying problems to solve. But why, the layman may inquire, is all this distinction? Why say power plant engineer, refrigeration engineer or office building engineer? Are they not all the same? Just engineers who "run an engine"? Yes, they are all classed under the same name and are the same from the outsider's pinnacle of observation, but like medical practitioners or lawyers some engineers specialize in one branch. It is too broad a field for one man to cover it all in a single lifetime. One doctor specializes on diseases of the heart, another on surgery; one lawyer may specialize in action of civil law, another may confine his attention to criminal procedure. The men above mentioned may properly be included in the broad application of doctors or attorneys although best known as specialists in one particular branch. So with the subdivisions of steam engineering. Engineers are most closely associated with that branch of which they have made a particular study.

Varieties of Training

The early lexicographers defined the term engineer as a man who "managed an engine" and we of the present day who follow the business of steam engineering can hark back, if not in memory at least as students of the history of steam engineering, to the time when this was literally true. Many of the older engineers of the last generation entered this field as graduates from shops where heavy machinery, such as pumping engines, perhaps boilers, and the old-fashioned slide and riding cut-off engines were built. After completing a course at the drill, lathe, planer and bench they received promotion to the assembling of machinery and were in due course sent out at erecting engineers. Many purchasers of large units of engines desired to retain the services of these men because of their familiarity with the new installations. This school of engineers were thorough mechanics, artists in the use of the scraper and file, and past masters in the work of assembling and installing machinery. The fire room was another fertile field from which engineering material was drawn; at least a beginning was made here, perhaps not as fireman at first but as coal passer or general utility man about the plant. By successive stages of promotion as the men were developed by experience they became valuable assistants in the plant and at last were included in the list of engineers.

It may be worthy of note that the initial training of these two classes of men was somewhat at variance, the graduate from the machine shop working backward, as we might say, from the engine room to the boiler room, and the fire room graduate following the evolutionary process in the opposite direction.

It is perhaps unnecessary to say that these were what are commonly termed practical men. They were good mechanics and men of horse sense; their education was not garnished with a finishing off course in an engineering school; their knowledge of the technique of steam engineering was limited; perhaps there were a few who knew the rudiments of steam indicator practice, but they were the exception rather than the rule, and the man who boasted of the possession of an indicator and reducing motion was looked upon as an oracle by his less fortunate engineering friends. He was the recipient of numerous invitations to come over to the other fellow's engine room and take some "cards." Many a Sabbath was desecrated in filming the antics of some antiquated specimen which was looked upon with eyes of affection by the engineer in charge. But what a change has been wrought in engineering practice in the years which have intervened. Measured by our standards, power plant engineering was then within short reach of the primitive stage. The development of electric lighting machinery had much to do with defining a line of demarcation which separated the old order from the new. Modern methods are in the ascendency and the World's best brains are turned to solving steam engineering problems.

The stationary engineer must be a student if he contemplates being a factor in the game. That the slacker will be lost in the shuffle goes without saying. Education is in the air; these are halcyon days in the engineer's career. The older generation of engineers can be forgiven if they were just practical men devoid the finer technique of the business. It was not their good fortune to have the opportunities for study which are now presented to us. That the successful steam engineer of the future will be a composite of engineer, draftsman, electrician, chemist, executive and business man is indisputable. Everything points in this direction,—the man who can "run an engine," and this as a limit will be caught in the swirl of the eddy currents and eventually be landed high and dry upon the bank where he will no longer be a participator—a spectator only. Fortunate indeed is the young man who can take a course in mechanical engineering at some of our better known scientific schools. He will not know all there is to be known about steam engineering and allied subjects at the time of his graduation, even though he take a post-graduate course, for as a well known college president once said, "We do not pretend to make finished material out of our graduates; all that we purpose doing is to 'teach them to think systematically.'"

For those who never have had, and possibly never will have, the doors of a college thrown open to them for the study of the scientific end of steam engineering there is no cause for despair; there is always an opportunity presented to him who shows a disposition to learn, for with evening schools of every kind and description, college extension courses, correspondence courses, an extensive supply of engineering literature which can be brought to our door with little trouble or expense, privately conducted engineering schools, vocational schools, evening drawing schools, and others in almost endless variety, it is hard to picture a condition where a disposition to obtain knowledge cannot be met.

We are never too old to learn. It may be that with the passage of years we find it harder to absorb and retain technical information than we did in our early twenties, but this should act as a stimulus rather than as a deterrent.

But no matter in what school we receive our engineering education, whether it be through the means of a full course in a technical institution, a completed scholarship in the school of hard knocks, or any of the ramifications or amplifications of both, we cannot afford to withdraw selfishly into a cocoon and isolate ourselves from the society of our fellow engineers. There is no better, no more practical course than that of social intermingling, the heart-to-heart way of extracting information and giving a little in exchange for what we receive.

Facts of the Future

EVERYONE knows that the coal resources of the world will not last forever, and speculation as to our future source of heat is a matter of some interest. The world's supply of coal will not last forever and at the present rate of exhaustion a few hundred years will find coal playing in the role of a more or less semi-precious mineral. Fuel oil, too, will be placed in the same category.

The internal combustion engine may well be the means of solving at least a portion of the problem, and Old John Barleycorn will be resurrected to a more useful life. When it is considered that almost any waste vegetable product can be converted into ethyl alcohol, it is readily seen that a source of power becomes available almost inexhaustible in extent. Waste from the products of the forest and field and vegetation of other types will serve to provide at least a portion of the fuel necessary, and where water powers are not available the internal combustion engine will reign supreme.

The suggestion of Sir Oliver Lodge to the effect that an excavation be made some ten or twelve miles deep has much to commend it from an investigator's standpoint, nad wells of extreme depth might, perhaps, supply us with heat. The suggestion for the digging of a pit of this depth has been mooted before by the "Khan," a newspaper correspondent, whose articles appear in some Ontario dailies. In his case the suggestion was made that a bit of the money spent by the nations of the world on armies and navies be used for the hole, a suggestion which might be forwarded to the League of Nations.

Solar energy can be utilized by those in the warmer climates, and the deserts of the world will bloom like a rose though, perhaps, not in a Biblical sense. At the present time, with comparatively cheap fuel, solar energy does not seem to be a commercial source of energy.

Inter-atomic energy, ever since the discovery of radio-active matter, has been thought of as a possible source of energy available for the future. With the fuller knowledge regarding the composition of matter now becoming available through research work something may be done with this source of energy in harnessing it for man's use.

A Joyful Thought

There is a keen, a subtle joy, in autumn's cooling clime, that makes it quite a pleasure to tear off yards of rhyme. We sing no more of summer days, of rivers or of lakes, of squattin' on a piece of rock just where the breaker breaks.

Nor yet of strips of wooded land, of cottages nor camps, with a hundred bugs and spiders and a dozen kinds of ants.

Begone such things, there, flee away, you're but a memory now—likewise the country scenes as well of piglets and of cow. We think of sterner things this month, of taxes and of coal, there's window sash and double doors to rend and vex the soul.

And underwear as thick as pie, it costs like silk and plush, to cover up the system from the snow flakes and the slush. But let us sing in joyful way, oh cheery be our tune—and blast it out at morning time, and then again at noon.

While seasons come and seasons go, there's recompense for each, the spring time has its budding tree, the fall its squash and peach. But, ah, to us, the thing that is of all things wondrous fine, concerneth not the things we see, nor things on which we dine.

We blush almost with modest joy to mention this here thing, of which we're moved upon this day to versify and sing. But when the warming rays of Sol get on their northern slants, your winter coat will cover up the patches on your pants.—ARK.

The Engineer of To-morrow

Address by Fred W. Raven, of the N.A.S.E., before the C.A.S.E. at Brantford

MR. PRESIDENT, officers and members of the Canadian Association of Stationary Engineers. It is indeed a pleasure to again visit your honorable body in convention assembled. Since a year ago, many things have happened. The great world's war has closed and the reconstruction period confronts us. The future holds much in store for us all, and especially for the engineer. To those who have fought for us, we honor. To those who have made the supreme sacrifice, we commend to God's Holy keeping.

To be worth anything to-day a man must be able to do something; he must have character and ability to stand on his feet and face the world. To command men, a man must first command respect and must be confident that he is equal to any emergency He must not lose his head or become rattled, nor fly off in a temper. The man who feels that his job is larger than he can manage is naturally nervous and irritable. He is conscious that he may be landed in a hole at any moment, and so he frets and fumes and keeps others upset and ofttimes ready to blame anyone for his own shortcomings. The man who is bigger than his job is always cool and confident that he is equal to any emergency, and never becomes rattled. No man can take out of the world more than he puts in. Many have tried it, but failed. It still remains true the "man must earn his bread by the sweat of his brow."

And so it is with an organization, it must have character and stability, and when a body of men organize, whether for honorable or lawful purposes, it is no more than right that they give to the public the reason and necessity for such organization. The Canadian Association of Stationary Engineers, having no objects that can be criticized, no plans not warranted by common sense, no desires not in accord with the demands of justice, we believe that it is only right and proper you give to the people of this community the reason for your existence. Your ranks are filled by competent men who believe that by a thorough knowledge of their profession, gained mostly by practical experience, they are better able to deliver to their employer and the public that efficiency which brings natural remuneration for services given, coupled with safety and conservation of our natural resources. If the North American continent is going to be the workshop and market of the world, the man of the hour, "the engineer," must be a steady, sober and industrious operator. With our shops, factories and buildings filled as they are with very valuable machinery and highly-paid workmen, it behooves the engineer and manufacturer to get closer together. The engineer, of all employees, is the best man for the manufacturer or employer to get acquainted with, and any employer who neglects this warning will fail to compete with those who are far-sighted enough to see these benefits. Much trouble in the past, and much in the future could and will be avoided if the employer studies his men and the necessities of his plant. Visit the workshop with a nod and a smile of greeting once in a while, and see the results that will come from it.

During the past generation engineers have placed a stamp on the world more marked than any other group of men. The engineer's knowledge is not only needed in the engine room, but in public affairs more to-day than ever before. Public activity must be carried on by groups of men to be effective rather than by individuals, therefore, if an organization of engineers is a benefit to a city, or province, or to themselves, an organization of manufacturers, taking an active interest in such an organization as this, must be the best of its kind and bring beneficial results to all concerned.

I sometimes wonder if we are doing all we can for our organization, or, if we get out of it all that is possible. The man that does his duty to his organization cannot fail but obtain great results for himself and all connected with him. An institution of this kind ought to appeal to all thinking engineers on account of the great good it can do. Our meetings need not be on education all the time, we should not take everything too seriously, or too lightly, but rather our meeting should strike that happy medium, that will enable us to gather in all necessary knowledge and sunshine that comes our way, and at the same time dispense it where the clouds hang lowest and the shadows are the darkest.

No institution, not even a fraternal one, can long exist without a substantial foundation. There must be something that appeals to the membership, real, strong, substantial and enduring, with a foundation that means personal liberty and the development of human character to a standard of excellence and efficiency. It is fit and proper that it should be so in this organization because of the commanding position it occupies in the engineering world.

When a man strives and lives with that part of himself which treats others as he would be treated himself, he is living a life of the best example. He is at that turn in the road where life seems the brightest and he cannot help but be happier, bigger and better. When a man keeps in his mind the Golden Rule, which to my mind precedes all creeds, all beliefs, it points the way to new thoughts, new teachings, and when a man is at peace with himself and with his neighbor, every sound suggests music and the clouds of frenzy and hate fall asleep under this beautiful June sky. Every flower recalls the perfume of earlier days, the hum of the bee as it weaves its winding path from flower to flower, will bring back the happy childhood days and the song of the birds.

Education is one of the greatest avenues to personal happiness, success and wealth; without education, life is without a future, so when a man strives to educate himself in our profession, and the general knowledge of the world, I have no fear for his future, no matter how high he climbs. Fame, fortune and favor have wings, but with character and education it develops the citizen and makes a nation.

Do not be afraid of anything in this world when you think you are right. Fear makes you doubt the very ability and talent you possess, and literally robs you of so much a year in both material gain and mental development. Do not be afraid to bring out your own individuality; a man strong in himself may make a weak imitation of someone else. We do not consider anything particularly as all roads lead to Rome; never mind if you choose a different one from your neighbor, providing you get there without loss of time. Do not be afraid to tackle any problem which seems hard at a glance—look it over again and again. Do not hide your light under a bushel, no matter if the light be even a small one. The greatest importance is to keep it burning—give it room—feed it well, and some day it may enlighten the world.

It is not in the nature of things that all men should be equally successful, but we should never lose sight of the fact that a small man's part is of equal importance relatively, as that of the greater. Employment and happiness are associated together, just as naturally as the sun with the day and the moon with the night, just so much as we make our employment productive to that extent that we can also take a greater interest in our surroundings. To the man who accomplishes less than he ought to, the world seems hard and unyielding, but it lavishes contentment and plenty on him who finds his happiness in thorough, earnest and vigorous prosecution of a work made successful by his own untiring efforts. To him who gives freely of his knowledge, much is received in exchange. The world will appear more cheerful, the leaves of the trees greener, and the flowers brighter to him who occasionally thinks of his fellowman.

Questions and Answers Relative to the Act and its Regulations

Relative to the Act and Its Regulations

Question 1.—I am thinking of starting as a fireman in some power plant, or other place where steam boilers are used, and would like to know just how the Graded Certificate Act would affect me, and whether it applies to all firemen?

Answer.—If you start as a fireman, or are firing at the present time in a power plant of less than 50 boiler horsepower, or in a plant where the boilers are operating at 20 lb. pressure, or less, a certificate is not required. Nor is it required if you are firing on a locomotive, steamship or agricultural engine or boiler. If you are firing, or going to fire, a hoisting engine boiler you will come under the Act and must hold a certificate, unless the hoist is located at a mine or quary, in which case you are exempt. Except for the particular classes of work exempted above, all firemen must hold a fourth class certificate.

Question 2.—I am a night watchman and have a friend who is thinking of becoming one in a nearby plant. Do I come under the Graded Certificate Act?

Answer.—Yes, if you are night watchman in a plant of 50-boiler horse-power or over, and carrying over 20 lbs. of steam. The same exemptions apply as to firemen, although in your case your position won't be such that you are liable to be night watchman, etc.; on locomotives, etc.

Question 3.—Is any period of training allowed to fireman before they are required to take out a certificate?

Answer.—Yes, six months, at the end of which time the fireman must present himself for examination.

Question 4.—What certificate must a fireman or watchman hold?

Answer.—A fourth class certificate will be required.

Question 5.—Is any period of training mentioned in the Act and its regulations?

Answer.—No; no period is mentioned either in the Act or in the regulations, but this will be subject to the ruling of the Board.

Question 6.—What sections of the Act and its regulations mention firemen and night watchmen?

Answer.—Sections 5 and 11 of the Act, and paragraphs 2, 66, and 40 of the regulations.

Question 7.—Who all must hold certificates under the Act and its regulations.

Answer.—Subject to the exemptions set forth, all engineers in charge, all engineers operating under the engineer in charge, firemen and night watchmen, must hold certificates.

Question 8.—What are the exemptions?

Answer.—Plants having less than 50-boiler horse-power, plants operating at less than 20 lb. pressure, locomotives, steamships, agricultural boilers, and only those hoists which are used in mines or quarries.

Question 9.—In plants which come under the Act, who are not required to have certificates?

Answer.—Firemen with less than six months' experience, workmen acting under the personal direction or supervision of any engineer holding a certificate under the Act and who is in actual charge of a steam plant, or to the employees of engine builders or steam plant contractors engaged in installing, setting, or testing a boiler or steam plant. This does not apply to hoisting engineers, and note the distinction between a workman under the actual supervision and direction of a qualified engineer and a person operating under the engineer in charge. That is to say, coal passers, cleaners and laborers working in or around power plants are exempted from the workings of the Act, but firemen, night watchmen, and engine room employees, come under it as defined in the regulations. The charge engineer has to have a certificate of the proper grade for the operation of the plant as specified in the regulations, while those under him are only required to have fourth class certificates.

Question 10.—What certificate must an operator hold who is under the direction of a chief holding a certificate?

Answer.—He must hold a fourth class certificate.

Question 11.—How is the boiler horsepower calculated?

Answer.—Under the Act a boiler horsepower means the evaporation of 34 lbs. of water per hour from and at 212 deg. Fahr., or expressed in heating surface—15 sq. ft. of heating surface for return tubular boilers—12 sq. ft. of heating surface for locomotive type boilers, and 10 sq. ft. of heating surface for water tube boilers.

Question 12.—Has the horsepower of the prime mover, whether engine or turbine, anything to do with the Act?

Answer.—No. Horsepower throughout the Act means boiler horsepower only.

Question 13.—Does an engineer in charge of a plant with power supplied by electricity from an outside source, and steam used only for heating at a pressure less than 20 lb., come under the Act?

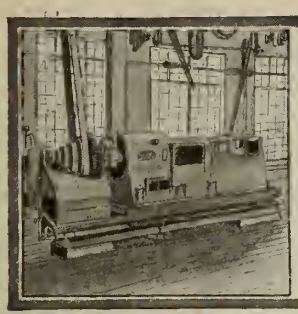
Answer.—No, unless steam is generated at a pressure greater than 20 lb.

Question 14.—What are the requirements for a fourth class certificate?

Answer.—The applicant must have had at least six months' initial experience as a fireman or otherwise. He must be of at least 19 years of age, of good character and sobriety, must be a British subject, or must have resided in Canada for one year.

Question 15.—What kind of an examination is set for a fourth class certificate?

Answer.—It is oral and practical in its nature. The main purpose of this examination is to determine the candidate's familiarity with the apparatus under his care and to ascertain his knowledge of its proper care. Steam boilers and pumps are what his examination will be based on, and knowledge of safe operation will be required. Hydraulics is mentioned in the Act and this will be limited to a knowledge of pump operation, valves, etc., and will be elementary in nature.



NEW POWER PLANT EQUIPMENT

A UNIQUE AND DISTINCTIVE LABOR-SAVING TOOL

LABOR-SAVING, time-saving, production-improving machinery and tools are fast becoming dominating factors in all industries.

The humble jack, in the form of the No. 328 Simplex Pole Pulling and Pole Straightening Jack, occupies the unique and distinctive position of being the only jack especially intended for and successfully operating under all conditions of pole construction and maintenance work.

It was designed at the suggestion and with the assistance of engineers and other officials of the leading telephone

and telegraph companies in the country for the express purpose of pulling and straightening poles for telephone, telegraph, electric light, power and railway companies, municipalities, and other public utilities having pole equipment.

Patents pending on this jack have recently been allowed, with broad claims, and will shortly be issued.

So successfully does this jack handle every phase of their construction and maintenance pole work that several hundred such companies throughout the country have adopted it as standard equipment.

As indicative of this great economy accompanying this unusual jack's service, it is claimed that with it one or two men can pull the largest pole, whatever the depth, soil or season conditions, in a fraction of the time it takes the usual gang of five or six men to do the work. Also, one man with this tool is said to straighten a pole in one minute, that usually takes several men several minutes to perform.

This jack is constructed of the very best materials and along rugged lines, and so designed that in both raising and lowering, its operations are so perfectly controlled as to insure absolute safety to pole, overhead lines, and other equipment, and operator.

This jack's various exclusive and distinctive features, above outlined, equip it to safely, economically and efficiently handle every phase of the varied, extensive and exacting pole operations of the largest public utility companies.

The high cost of labor in their construction and maintenance operations is causing public utility companies to give, more than ever before, serious attention to more economical and effective ways and means of meeting these high maintenance costs.

In this service the No. 328 Simplex jack mechanism is proving itself "a friend, indeed, in time of need," by heavily reducing the labor and other costs, at the same time very materially increasing pole-handling efficiency all around.

Those concerned in public utility pole construction and maintenance work who are not conversant with this unusual tool and the niche it has carved for itself in public utility pole efficiency and economy will find it a most interesting and instructive subject.

The Simplex No. 319 emergency jack is another Simplex tool of distinctive and exclusive design, very similar to the No. 328 pole jack, and which is adapted to an almost unlimited range of general utility service. Like the No. 328 Simplex above described, this jack operates to any angle at full capacity. This exclusive service ability in connection with its several different lifting and pushing points and attachments, enables it not only to meet any and every emergency that comes within the scope of jack service, but vastly wider range than performed by any and all other jack construction. In fact, so perfectly adapted is this jack to moving every object that needs to be pushed or lifted, that it well may be termed the jack of a thousand uses.

The unusual versatility and efficiency of the No. 310 Simplex makes this jack worthy of the interested attention of very many not concerned or interested in ordinary jack service.

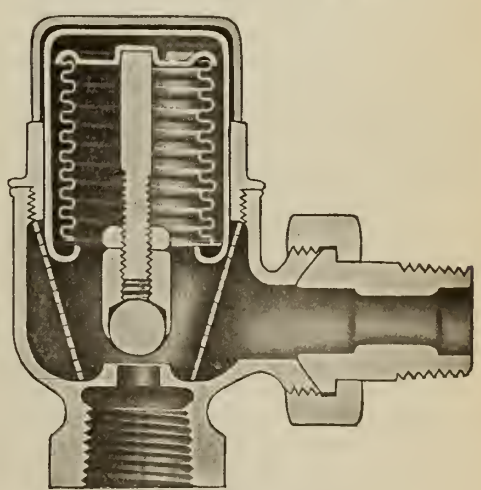
The manufacturers of these jacks, Templeton, Kenly & Company, Ltd., 1020 South Central Avenue, Chicago, Ill., will gladly supply interesting and instructive information and literature on either or both of these jacks.

NEW RADIATOR TRAP

The "Sarco" radiator trap is a development of the "Sarco" steam trap used everywhere for high and low pressure. It uses a spirally corrugated tube of large diameter. This, with the outer case, forms the expansion chamber, which contains a volatile liquid. The inside of the diaphragm is directly exposed to the steam or vapor. This arrangement results in quick and wide opening and closing of the valve. Slight change of temperature within the trap, due to condensation collecting in same, will give a wide open movement of the valve and permit of the prompt discharge of condensation.

We direct special attention to the Sarco diaphragm as it is unique in design and conspicuously better than any hitherto used in radiator work. Spiral corrugations insure that when the tube is expanded or contracted the movement is equal on every turn of the spiral. Annular corrugated tubes on the other hand contract and expand to the maximum degree at a given point; the movement at that point being considerable, the life of such tubes is restricted. With the Sarco spiral the movement is scarcely perceptible at any turn of the tube and the life of the diaphragm is constantly much longer than with the annular design.

Reference to the illustrations will show



NEW SARCO TRAP.

other special points, notably the new valve head, which is a bronze metal ball, freely turning in a socket. This insures a perfect seat and offers a wearing surface many times greater than that of any other type of valve on the market.

The construction also permits the pro-

vision of a strainer of ample surface. The importance of this need scarcely be emphasized. It effectively prevents clogging and protects the valve head and seat, eliminating practically all wear. The strainer has a discharge area some ten times that of the valve itself, and there is, therefore, little danger of stoppage, and there is no need for the cleaning of the strainer except at long intervals.

With this strainer the heating system can be started up at the beginning of the season without any danger of valves being blocked or injured by scale or rust.

The new Sarco radiator trap is tested and adjusted under conditions which reproduce the working conditions when installed. It is a factory-adjusted trap and requires merely to be connected to the radiator and to the return exhaust line. It will work on any degree of vacuum and on any steam pressure up to 20 pounds per square inch without strain or without readjustment.

Correspondence Re Graded Certificates

After years of agitation, an Ontario Government has granted a graded certificate act to the stationary engineers of Ontario. The act is one which has been needed for a long time, and presumably the engineers are to be congratulated on having secured it. However, after the first enthusiasm wears off, and it is examined more closely, cause for rejoicing is not so apparent.

The writer is considering the legislation from the point of view of one who has had considerable experience in the operating of industrial steam power plants, and knows exactly what the requirements and rewards of the position are. The question arising in my mind is this: Under the legislation as it stands, what inducements are there to attract a young man to power plant engineering.

The act follows in some respects the law in force for some years past in Quebec, while some portions of it are based on British Board of Trade rules. It perpetuates some of the objectionable features of the Quebec legislation, while it outclasses in severity in one respect the British Board of Trade, upon whose regulations nearly all other laws are based.

One of the points to which strong exception can be taken is the renewal feature. Why should a man who has successfully passed an examination and proved himself to be competent under the law's requirement, be compelled to pay yearly for the privilege of remaining competent? "It's only a dollar," some will say. Quite so, but why the renewal at all. If a man is competent in 1919, why is he not competent in 1920. He is, but the Government has to get revenue to keep up the Department. Therefore, the engineer must pay it. Why should he? The graded certificate is a protection for the manufacturer and the general public. Should not they contribute to the cost of keeping up the examination board. The yearly renewal fee takes the thing out of the realm of a certificate, and makes it a license. In other words, the engineer is taxed so much per year for the privilege of earning his living. Furthermore, the lowest-paid man is charged the same license fee as the highest but one.

The fee for examination is right and necessary, but, why saddle the candidate for a fireman's examination with the same fee as the candidate for a second class engineer's certificate? In the nature of things the examination cannot be as great a demand on the examiner's time in one case as the other. Furthermore, the man with the fourth class license cannot demand the same reward for his labor as the man with the second class.

However, the foregoing points are perhaps minor ones to many people's minds, though to the writer's they are real subjects for criticism. When in charge of a plant, there was no item of my personal expenditure that was so grudgingly spent as the renewal fee for my certificate, or license.

Now, let us take up the case of a hypothetical young man, who is starting in to work next Monday as a fireman. In the hopeful way of youth, he is picturing the day when he will have the proud privilege of spending 24 hours a day on the plant as chief. He finds that after six months' experience he is examined for a fourth class certificate, which will entitle him to operate under a certificated engineer in a plant of 50 h.p. or over. He must then put in 1½ years as a boiler engine room subordinate before he is entitled to examination for a third class certificate. Having successfully passed this ordeal, a further three years' servitude is demanded before he can become a candidate for a second class examination. That means that he must look forward to five years' steady work from the time he started in before he can obtain a second class, and take charge of a plant of 150 to 300 h.p. That is very good, and will ensure a man having experience before getting charge of a plant of any but very moderate size. It is when he wants to realize his ambition of being a first class man that he hits a snag. He finds that he is condemned to seven years in a plant of 300 h.p. or under before he can obtain a first class. He must shown seven years as chief or as operating engineer. What does this term operating engineer cover legally? I have always understood that the operating engineer was the man actually in charge of the power house. However, a fourth class certificate entitles a man to operate, under a chief, a plant of 50 h.p. or over. That means a plant of indefinite power. We take from that the suggestion that operating experience under a chief is as valuable as experience in absolute charge. However, this clause may be interpreted, a man who has succeeded in five years in obtaining a second class certificate, and wishes to take charge of a plant of 305 B.H.P. must wait for five years before he can be proun)unced fit to do so. On the other hand, he can, with no further delay, take charge of a shift on a plant of 3,000,000 horse power, if he can find one.

The writer was asked recently by an old member of the C.A.S.E. how a man who had been fifty years at the game would be affected by the legislation. The answer I gave him was, "The old man will be all right, but the young one has a hard row to hoe."

Ten years is too long an apprenticeship to serve. The probationary time should not be stuck on the end when a man's experience is ripening. If put on anywhere it should be at the beginning of the time, when he is young, and expects to serve an apprenticeship. If a man is fit to be responsible after two years as an oiler or fireman to take charge of 150 h.p., why should he take five times as long to be fit to take charge of a plant of 305 h.p.

After obtaining a second class certificate, one year more should be ample time to qualify for a first class. That would mean six years, and if a man isn't fit after six years to qualify, he won't be much better after four more.

Was this ten-year clause put in by the wishes of the engineers themselves, or by any particular portion of them? I would like to hear some opinions of engineers on this phase of the act.

By T. H. FENNER.

A new practical application for the metal selenium, has been suggested by a French scientist, L. Ancel. It is the use of selenium cells as smoke recorders in chimneys. A selenium cell is mounted on one side of a chimney or flue; on the opposite side is fixed a lamp.

The amount of light falling upon the selenium and hence the resistance of the cell will depend upon the density of the smoke in the flue; the fire can, therefore, be controlled by the galvanometer records. Ancel describes the device very briefly; he mentions that the cell should admit of easy access so that the smoke settling on the glass cover of the cell may be wiped off, and also that selenium cells are very sensitive to infra-red heat rays as well as to light. It is not settled yet, in fact, whether the light effect on selenium is not essentially a heat effect; that point would in a way militate against the reliability of the selenium cell to act as smoke recorder. Another novel application of selenium cells, mentioned by Ancel, consists in controlling the contact sulphuric acid process by the degree of the transparency of the gases in the reaction tube. Ancel, however, does not give any technical data.

The Operators' Point of View

ORAL OR VIVA VOCE

By Llewellyn

How One Engineer Secured His Certificate

SAY, chief, what does the word oral mean?

Oral, or viva voce, means by word of mouth, that is, an oral examination is where the examiner asks questions and you just tell him the answers instead of writing them. Quite simple, is it not?

For instance, several years ago, some half dozen young chaps, myself included, waited in the hall to be ushered into the sanctum one by one to go through the ordeal, when suddenly my name was called. I went in, and with my knees almost knocking together and my heart thumping like a steam hammer, I felt rather confused when face to face with two examiners who looked at me in such a manner as to suggest, what can we do for you?

With quite a struggle I succeeded in recovering my voice sufficiently to break the silence by saying, "Good morning, gentlemen," and the following dialogue took place:

"What kind of boiler have you at your plant?"

"A horizontal return-tube boiler, with ——."

"Yes. What ornaments or fitting are there on the front end?"

"There is the gauge-glass and try cocks, the ——."

"What in the world do you want a gauge-glass for?"

"So that you may know the height of water in the boiler."

Then they sat back in their chairs and had a good laugh at me. I was indignant and was about to make a remark, when, remembering that self-control is one of the essentials of an engineer, I kept silent.

"You say you have water in your glass. How much?"

"Usually about two-thirds full."

"Then what is in the rest of the glass?"

"Steam."

"How do you know there is steam there? Can you see it?"

"No. Steam is an invisible gas, but if you open the drain-cock at the bottom the steam will force the water out of the glass. The top of the water column is connected direct to the steam space of the boiler."

"I see, so when you want to know if there is any steam in your gauge-glass you open the cock and blow out the glass, eh? How often do you blow your glass out?"

"Two or three times a shift, depending on the condition of our feed water. If it is very vile, then oftener."

"Well, now, you tell us this, glass affair is to show the height of water in boiler; you also say it is connected to the steam space of your boiler. What kind of a rig is it, anyhow?"

"There are several designs based on the same principle, consisting of a metal column connected to the steam space on the top and to the water space on the bottom, so located that the centre of the water-glass gives a safe working level. The glass is secured to the column by a strong brass fitting having a suitable stuffing box, ring, and a nut, with the aid of a rubber ring, making a steam-tight joint. On the side of the column there are three test cocks and a ——."

"What are these test cocks for?"

"To give the height of water in the boiler in case your glass gets broken or becomes choked up."

"What are their location?"

"The lower one should be not less than two or three inches above the top row of tubes or highest point of fire line and the second cock not less than two or three inches above the first or at normal water level, and the top one about the same distance above the second one."

"So you only use these cocks in case something goes wrong with your glass?"

"Oh, no. They should be used two or three times a shift so as to keep them clear and prevent them getting choked up."

"Well, are there any other fittings on your boiler?"

"There is the steam pressure gauge and ——."

"How should the steam pressure gauge be connected to the steam space of your boiler?"

"By an inverted syphon, a pipe having one coil bent on it, or some similar arrangement whereby some of the steam may condense into water so as to protect the delicate mechanism of the gauge being injured by the high temperature of the steam. A cut-out cock to be placed between the syphon and the boiler unconnected with any other fitting."

"Yes, but what is this gauge for?"

"This gauge indicates what pressure you have in your boiler."

"Oh, I see, if your gauge shows 100 pounds per square inch you have absolutely 100 pounds pressure per square inch in your boiler?"

"No."

"Why, then?"

"Because absolute pressure is figured from a perfect vacuum."

"What are you giving us now?"

"Well, the pressure indicated by the gauge is the pressure above the atmospheric pressure, which is about 14.7 pounds per square inch."

"Suppose your boiler pressure was 5 pounds below the atmospheric pressure, what would your steam gauge read?"

"The pointer would be at zero and you would have a partial vacuum in your boiler."

"Where would be a good place to have your feed water connection?"

"The arrangement should be such that the water will be discharged at the coolest part of your boiler. A convenient arrangement is to have the pipe enter the front end of the boiler about three inches above the top row of tubes; the pipe should be continued inside the boiler nearly to the back end and in such a manner as to discharge the feed water between the shell and tubes so that the feed water will be heated to a good temperature before being discharged into the boiler."

"How can you regulate the feed water?"

"By a stop valve on the feed pipe close to the boiler."

"Yes, but if you open the stop valve what is going to prevent the pressure in the boiler forcing the water and steam back to your feed pump?"

"There is a check valve just below the stop valve close to the boiler."

"What good will that do?"

"A check valve being a non-return valve will permit water to pass into the boiler but is instantly closed when the pressure on the boiler side is greater than that on the pump side."

"What do you consider one of the most important fittings on a boiler?"

"The safety valve."

"Why do you have a safety valve?"

"Because when the pressure in the boiler reaches a certain point it automatically opens and releases the pressure thus preventing an explosion."

"What kind of valve have you between your boiler and safety valve, a globe valve or a plug cock?"

"No valve should be between. The safety valve must be connected direct to the boiler."

"What kind of stop valve do you prefer on you main steam line?"

"A self-closing stop valve situated on top of a riser about three feet high with a horizontal length to the header on main steam line so as to give flexibility and in case one of the boilers in a bat-

tery giving out the steam will be shut off from the disabled boiler automatically.'

"Suppose you got too much water in your boiler, what would you do?"

"Let some out by cautiously opening the blow-down cock."

"Where is the blow-down cock connected on your boiler?"

"To the bottom of the shell near the back end of boiler."

"What kind of valve is it?"

"A packed cock. Globe and angle valves are not allowed."

"Of course you only use this valve in case your water gets too high?"

"It should be used once a day at least according to the state of your feed water so as to blow out any sediment and to keep the valve in working order."

"You say if your water gets too high you can blow off some, and if your water gets too low, what then?"

"If the water gets too low the fusible plug would melt and relieve the boiler of dangerous pressure."

"Where should these plugs be located?"

"To that part of the boiler first liable to become overheated. In a horizontal tubular boiler about three inches above the top row of tubes in the back end. In the crown sheet of a horizontal fire box boiler. The lower side of the upper drum of a water-tube boiler, and the lower tube sheet of a vertical boiler are considered suitable places for these plugs."

Now I've got to get busy. Drop in again sometime, good-bye. So my friend left me after I had given him an idea of an oral examination.

C. A. S. E. BANQUET

Toronto No. 1 lodge of the C. A. S. E. held a most enjoyable function on Thursday, October 23, at Young's Banqueting Hall, Yonge Street, Toronto.

The occasion was the first annual dinner of the lodge, and about 130 people sat down to a good dinner at 8 p.m.

The members were accompanied by their wives and sweethearts, and a few invited guests were also present. These included Dr. Riddell, superintendent of the Trades and Labor Council, accompanied by Mrs. Riddell; Mr. Mosely, who has now been appointed to the Board of Stationary Engineers; Mrs. Mosely; Mr. Metcalf, chief provincial boiler inspector; Mr. T. H. Fenner, of the POWER HOUSE editorial staff, and others.

The entertainment, which followed the dinner was excellent and varied. Mr. Reed sang Scotch dialect songs with the skill of a Lauder; Miss Dean performed a brilliant piano solo; Mr Balmfirth, the indefatigable secretary, gave a reading, and later appeared in a sketch, assisted by several of the ladies.

The toasts were all honored in the wine of the country, namely, water. Mr. Balmfirth, after proposing the health of the King, which was loyally honored, called on Mr. Mosely to propose the health of the Government. Mr. Mosely acceded to the request, though, he said, it was difficult to know who was being toasted. Dr. Riddell responded to the toast, and in a well-chosen speech called the members' attention to the gratitude they owed the Hearst Government. Other toasts were "The ladies," proposed by Mr. Taylor and responded to by Mr. C. B. Turner; "Our guests," proposed by Mr. Bly, and responded to by Mr. Fenner.

The affair ended at midnight, everyone leaving the gathering with pleasurable feeling. Toronto No. 1 is to be congratulated on the effort.

ZINC FOR ELECTRICAL WIRES

W. K. Whippleman

(Copyright. All rights reserved)

The papers state that zinc is now being used in Germany for electrical conductors instead of copper, because of the scarcity of copper. How does zinc compare with copper as a conductor? If the conductivity of copper is taken as 100, the conductivity of zinc is 28.5. That is, zinc conducts an electric current only about one-fourth as well as does copper. In view of this it is apparent that zinc could not be effectively substituted for copper in most electrical appliances.

TRADE GOSSIP

The Pennsylvania Crusher Company, Philadelphia, have issued bulletin No. 1004, descriptive of their hammer crushers adapted for the fine crushing of bituminous coal.

The Chain Products Co., of Cleveland, Ohio, have issued a very attractive and useful catalogue, which is especially useful to anyone interested in chain products of any nature.

This book, known as their catalogue C30, consists of 111 pages, and is divided into three sections. The first is devoted to coil chain, the second to chain specialties, and the third to miscellaneous attachments. Several wire and chain tables form a closing part of this book, which should be in the hands of those interested in weldless chain.

In Barton Tp.—Firestone Rubber Co. will probably locate in Barton Township, just outside the eastern limits of Hamilton. A large tract of land has been secured, part for industrial purposes, and the balance for employees' homes. The Barton Township ratepayers are voting on a tax exemption proposition. In the meantime the Firestone Co. have leased the old Canadian Cartridge plant, Hamilton, and will start building the machinery there for the new rubber plant. Mr. Cook, formerly superintendent of Canadian Cartridge Co., is to have charge of the machine building.

Granby Starts By-Product Plant.—The Granby Consolidated Mining Company at Anyox, B.C., have now put their by-product plant in full operation. Toluol, benzol, sulphate of ammonia, and coal tar are among them. The coal tar will be shipped to Vancouver and resolved into pitch and creosote, and will be sufficient for all B. C. requirements in these lines.

Secure Power Supply.—The International Paper Company has just recently entered into contract with the Shawinigan Power Company to supply all the power requirements for the large new development at Three Rivers, Quebec. It was first thought that the Paper Company would undertake the exploitation of power generation on their own initiative, but after a thorough survey of the power situation, it was decided that it would be more successful and economical to purchase their power from outside sources. The ultimate horse power that will be required is problematical, as this will be augmented from time to time as the needs become greater. The initial output of the mill will be about 200 tons of newsprint per day, and this will call for about 20,000 h.p. The plant, when in operation, will employ about 1,500 men.

St. John, N.B.—Angus McLean, general manager of the Bathurst Lumber Co., and Major V. J. Hughes, of Montreal, manager of the Canada Iron Corporation, appeared before a meeting of the Provincial Government this week in connection with the plans for the development of water power on the Nipisquit River. The contract, Mr. McLean said, is to be carried out by Morrow & Beatty of Peterborough, Ont., under direction of Wm. Kennedy, Jr., hydraulic engineer. It is proposed to build a dam at Grand Falls on this river to develop 10,000 horse power, to be transmitted to Bathurst, N.B., for the operation of the pulp and saw mills and other industries controlled by the Bathurst Lumber Co. Two generators will be installed at once and arrangements made for the installation of a third, if necessary. The transmission line will carry from 50,000 to 55,000 volts and will be erected on steel poles.

Fuel oil is frequently spoken of as "crude oil," but this is incorrect, as the crude oil, that is, the petroleum oil as it issues from the well, contains certain light fractions of the petrol and paraffin series, which it is not only desirable to extract from the crude by distillation on account of their higher values, but which, if left in the crude oil and used as fuel would be a wasteful procedure, and further, would lower the flash point, which has been very properly fixed for fuel oil by British authorities, viz., Lloyds' Register of Shipping 150 deg. Fah., British Admiralty 175 deg. Fah., London County Council 175 deg. Fah. The crude oil is therefore subjected to what is known as a "topping process," which is a distillation which cuts out those lighter fractions, leaving a product having a calorific value of about 19,000 B.Th.U.s. per pound.

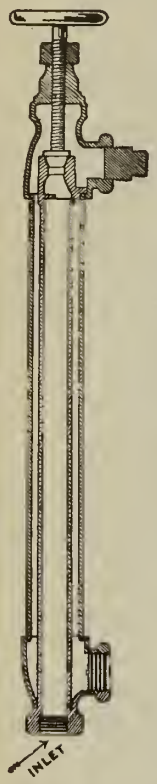
Requires Very Little Attention



Do you want efficient and reliable steam trap service without having to give the trap constant attention? Then adopt

The Long Patent Steam Trap

Has important features which CLAIM your attention. Absolutely guaranteed. The Long Trap is automatic and requires no valves except those which control the admission of steam to the apparatus to which the trap is attached.

The trap is regulated to work against any pressure between 1 and 200 pounds. Being open at starting, it cannot become air bound, this doin away with air cocks or vents — Does Not Freeze.

It is capable of draining from 90 to 1,500 feet of one inch pipe.

The Long Trap may be applied to drain steam mains, jacket kettles and separators, and can also be used in drying room systems.

If your dealer does not sell it write direct. No. 2

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 TO 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

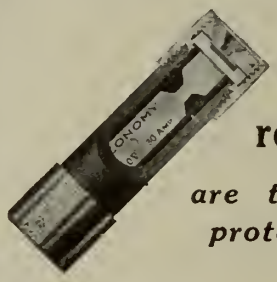
An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

WANTED — FIRST-CLASS ENGINEER TO take charge of steam plant; prefer a man with knowledge of Detroit Stokers, also one who has had some experience with electrical machinery. Box 154 Power House, 143 University Ave., Toronto.

WANTED—BY LARGE ONTARIO BOILER manufacturer, an experienced draughtsman, familiar with the designing of tubular, locomotive and stationary boilers. Box 153, Power House.

At the October meeting of the Canadian Railway Club, which will be held at the Windsor Hotel on the evening of the 14th, the subject will be Competition, Combination, and Co-operation, and will take the form of a lecture by Major S. T. Robins, general manager of the Dearborn Chemical Company.



ECONOMY renewable FUSES

are the RIGHT fuses to protect YOUR electrical circuits

—because they afford the right sort of protection; their reputation lends assurance that you can safely depend on them for accuracy of rating and all-around efficiency in operation.

—because they cut annual fuse maintenance costs 80% as compared with the use of one-time fuses, owing to the fact that an inexpensive "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

—because it's the work of a moment to replace the link and renew the fuse.

—because a good sized stock of "Drop Out" Renewal Links always on hand represents but a small outlay. *Write for Catalog 24*

Keep Canada Humming

Canada is running a great National Store.

Great Britain and other lands come here to buy our surplus agricultural and industrial products. These are the orders that are keeping Canadians busy and prosperous. That is where the money comes from that is paying our farmers for their surplus products and providing full pay envelopes for our workers.

But Great Britain and our allies are temporarily short of "cash." So Canada must extend them "credit" — just as any storekeeper extends credit to any customer whose financial standing is good.

The success of the Victory Loans 1917 and 1918 made possible the giving of these credits.

Continuation of these credits and the maintenance of our valuable overseas markets—depend upon the success of the Victory Loan 1919.

You will therefore plainly see how closely bound up with the Victory Loan 1919 is the prosperity of everyone in Canada, without exception.

Do not think your individual co-operation "does not matter."

It does matter!

Unless Canadians to the last man support the Victory Loan, it will not be the success that our continuous prosperity demands.

Let every Canadian do his share to keep things humming.

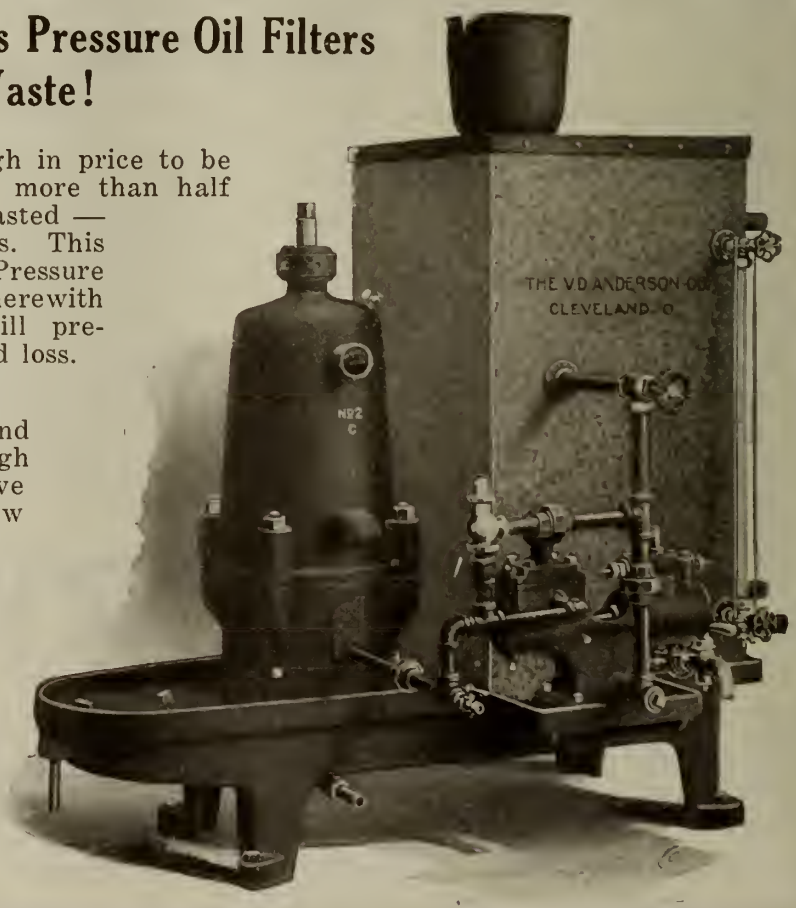
Why Waste Oil?

Anderson's Pressure Oil Filters Prevent Waste!

Oil is too high in price to be wasted. Yet more than half your oil is wasted — lost on wipers. This Anderson Pressure Oil Filter herewith illustrated will prevent this dead loss.



Place drip pans beneath engines and machinery. Then pass this oil through the **Anderson Filter** and you will have oil just as clean and as pure as the new oil you purchase.

You can use oil over and over again with the Anderson Filter. No other filter will do the work so thoroughly.

There are a few more points about the Anderson that we would like to take up with you. Pleased to have you drop us a line.

The V. D. Anderson Co.
West 96th St., Cleveland, Ohio

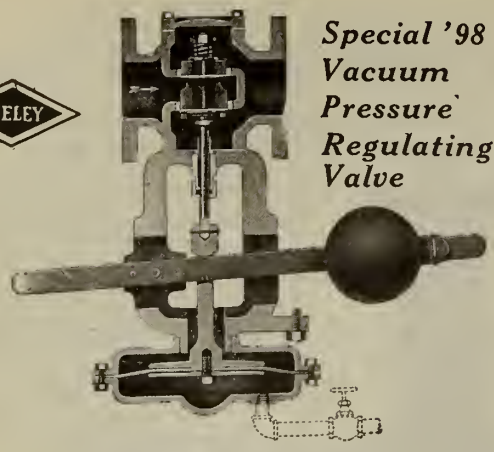
KIELEY



Special '98 Vacuum Pressure Regulating Valve

Responds to Slightest Fluctuation

The independent diaphragm feature of the Kieley Special '98 makes this type of valve especially appropriate for use in connection with vacuum or vapor heating systems, or any other service where close regulation is of importance. Both straight and differential patterns respond to slightest fluctuation. Maintains desired pressure at any point of heating system or supply mains by adjusting weight on lever. This valve is advanced in design. Let us explain it in detail.

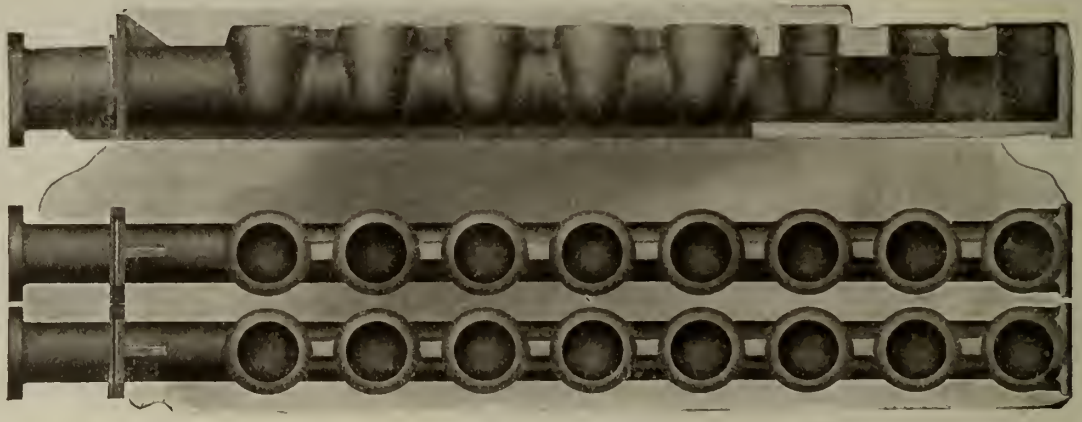
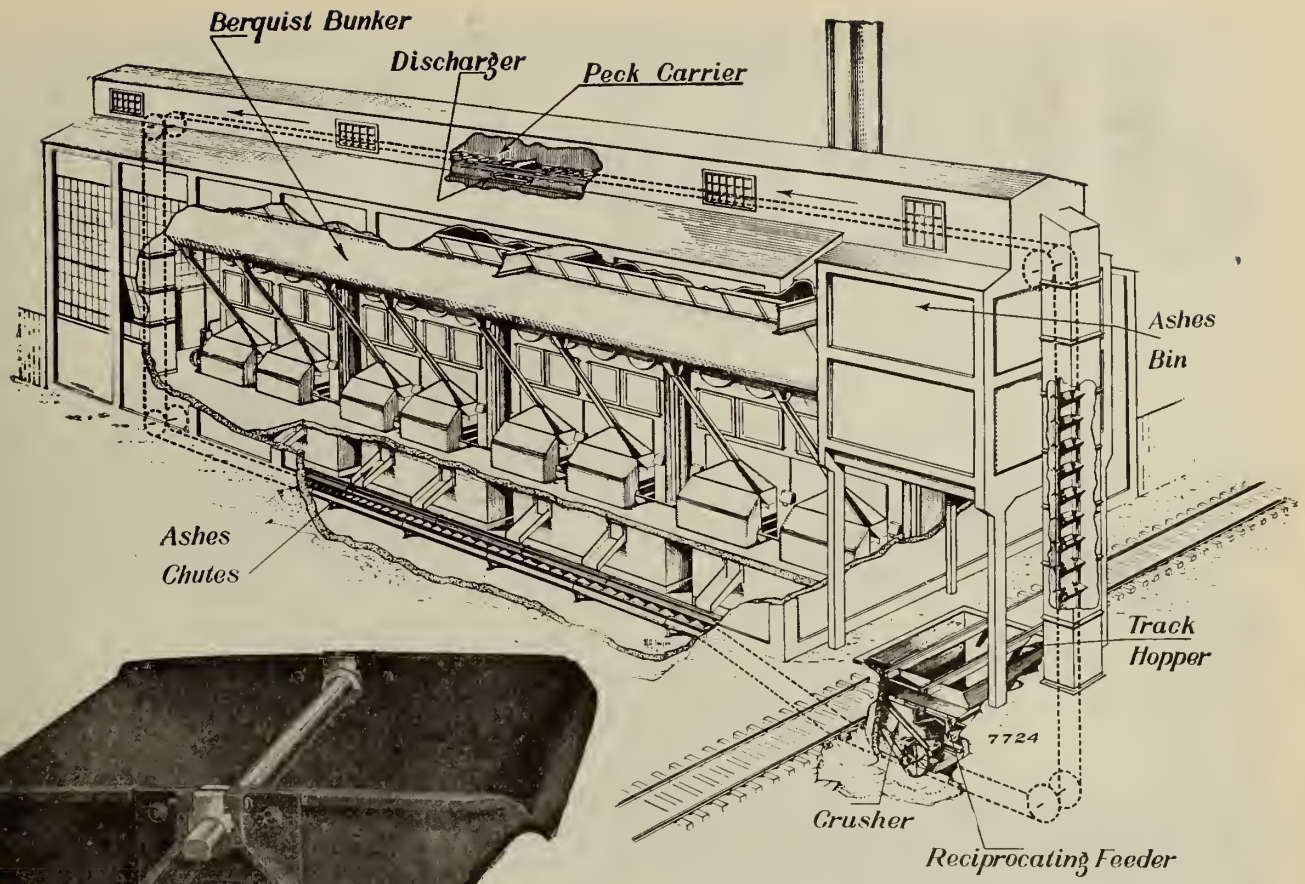
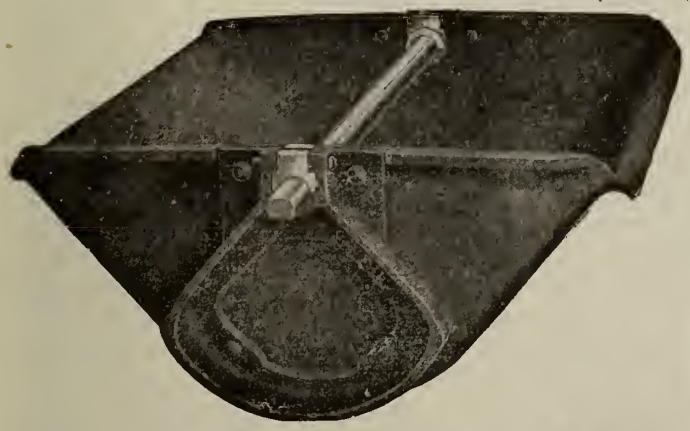
Bottom Headers Article No. 4



The bottom headers are provided with tapered sockets to receive the tubes as previously described. The ovoid construction, which is well illustrated by the accompanying cut, leaves an extra large space between the headers. This construction prevents soot collecting on the bottom headers and eventually blocking the space to the soot pit and also gives ample space for inserting a man's arm for adjusting the scrapers if this should become necessary. The end of the header is extended to pass outside the economizer and connect with the branch pipe. The headers are supported on collars cast at either end as shown in cut.

GREEN'S ECONOMISER, LIMITED.
TORONTO





LINK-BELT
Coal Handling Machinery

GRAVITY Bucket Carriers, consisting of a continuous series of buckets pivotally suspended between two endless chains, represent the highest development of the conveying art. As the buckets at all times maintain their carrying position by gravity, a single Carrier can transport material horizontally, vertically and again horizontally, or in any desired path.

The Peck Carrier, Patented, is the highest development of this type of conveyor—in its inherent design, details of construction, and accuracy of workmanship. It is the recognized standard machine for handling coal and ashes in modern power houses, as well as cement clinker, stone, ore and other abrasive materials.

Send for our Peck Carrier Catalog No. 320 and learn why the Peck Carrier is the superior of all conveyors for coal and ashes.

We also design and build elevators and conveyors for handling all kinds of material; coal and ashes handling machinery; coal crushers; chutes; screens; belt conveyors; locomotive cranes; grab buckets; portable loaders; electric hoists; Link-Belt and sprocket wheels; silent chain drives; transmission machinery, etc., etc.

Catalogs sent upon request.

CANADIAN LINK-BELT COMPANY

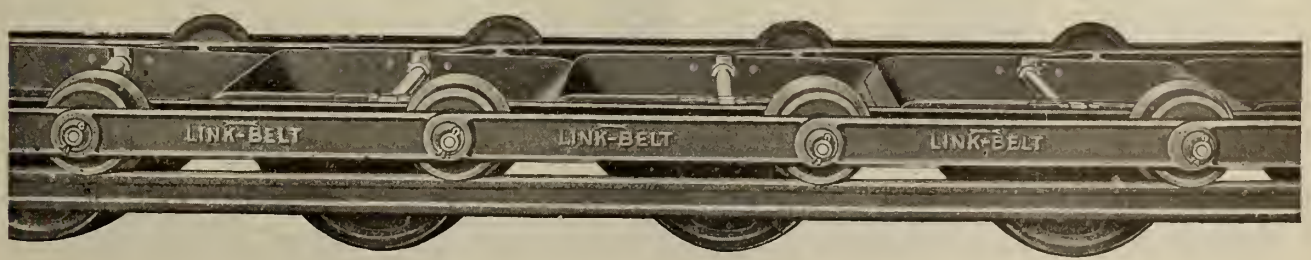
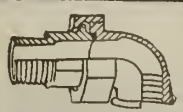
WELLINGTON AND PETER STREETS, TORONTO

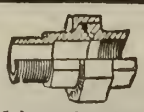


JEFFERSON

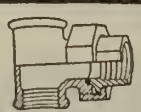
"Look for the name on the nut"



Union Elbow, an economizer of the most pronounced type. Also made all female.



Male and Female Union. Takes the place of an all-female union and a nipple. Makes a short connection.



Union Tee, with union on the outlet. Made also with male end on outlet.

The Guardian of the Pipe Line

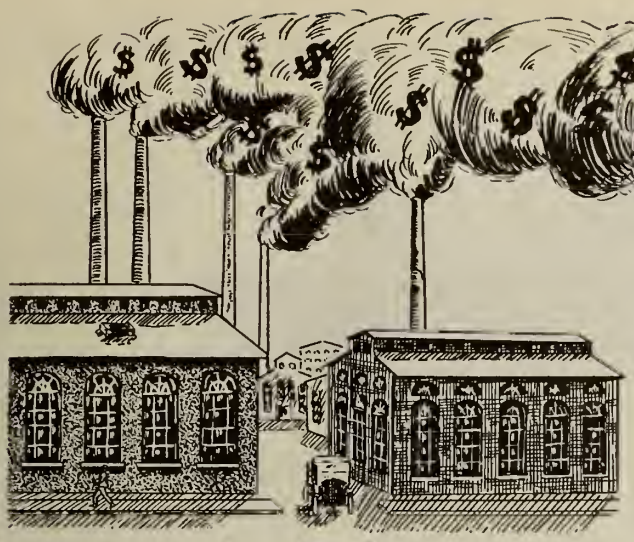
Above ground—in breakers and power house—below ground—in shafts and pump rooms—you'll find Jefferson Unions guarding the pipe lines from leaks and breakdowns.

Protect your plant from expensive shutdowns and costly repairs. Insist on genuine JEFFERSONS. It's easy to be sure because the name is clearly stamped on the nut.

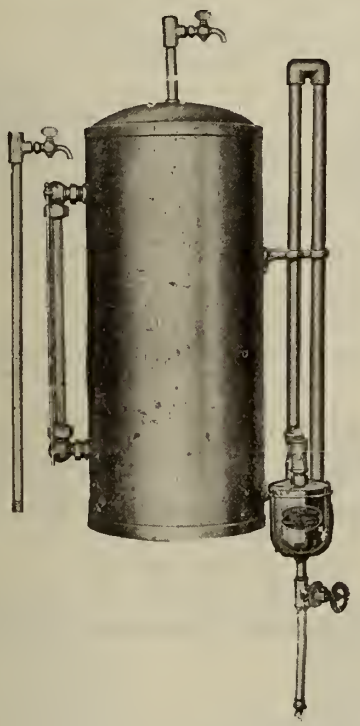
A "just-as-good" union costs about as much as a JEFFERSON—you pay as much or more to put it on the line and moreover you have the added cost of taking it out when it fails. Save this time and money—play safe and standardize on JEFFERSON UNIONS.

Write for our Catalog UNIONS.

The Jefferson Union Co.
Lexington, Mass.



Dollars Going Up In Smoke



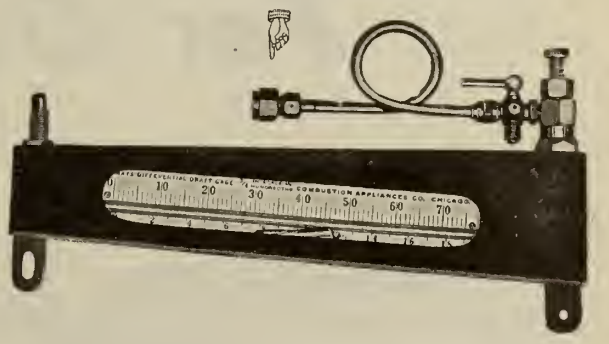
Give the Heat Units to the Boiler

HAYS combustion testing apparatus effects a huge fuel economy. It is a friend of the fireman and a very profitable investment for the plant owner.

It shows at once if draft is proper—if there are holes in the fire—if settings are leaking—if firing periods are improperly timed and other causes of fuel waste.

Gas Collector with water-flow regulator.

The Hays Differential Draft Gage indicates the draft over the fire or the drop in draft through the boiler.



HAYS Automatic CO_2 and Draft Recorders, Automatic Gas Collectors, Draft Gages and other Hays Equipments installed on your boilers keep you posted as to just what conditions your boilers are operating under.

Hays Combustion Efficiency Appliances are leading the way to increased efficiency in boiler firing, a most effective way in offsetting high coal prices.

Ask for our book, **"How to Build up Furnace Efficiency."** It tells how fuel is wasted, how to stop that waste and keep it stopped.

INSIDE FACTS

The cover and thermostatic disc are securely fastened together: therefore there are only two major parts to a Dunham Radiator Trap. The disc is of special composition phosphor bronze, enclosing a volatile liquid which is extremely sensitive to temperature changes over a wide range—10 pounds pressure to 15 inches of vacuum. No adjustments are ever needed: we do that at the factory.

The DUNHAM HEATING SERVICE

The above illustration shows all of the trap. Note the absence of loose parts in the path of flow: there are no sliding contacts, nothing to gum up, no guide or pin. The valve seats squarely. No wonder that the efficiency of the Dunham Radiator Trap equals its simplicity. *The complete details will interest you.*

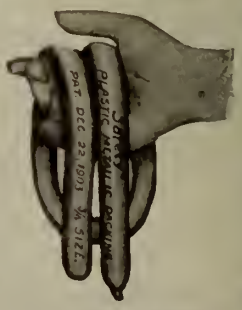
STEEL MILL PACKING CO., WINDSOR, ONT. Established 1899

AGENTS WANTED

Practically Frictionless



In Cotton Tubes

IT PAYS TO "STANDARDIZE"

Vulcabeston Red Fibre Sheet Packing makes leak-proof flange joints no matter what is flowing in the pipe—steam (superheated or saturated), oil, water, compressed air, acid or ammonia.

Why have the bother of a lot of different, special brands of packing for as many different flange joint uses—when the ONE packing—VULCABESTON—will supply all your needs? Standardize with Vulcabeston Red Fibre Sheet Packing. It is "the universal packing."

Thousands of engineers are proving by reduced packing costs and savings in re-packing labor that it pays to "Vulcabestonize."

RALPH CONNOR

On "The New Canada and Its Needs"

RALPH CONNOR, the famous Canadian novelist, who served for several years at the front and saw the war from many angles, is convinced that Canada must be prepared to make important changes if she is to profit by the lessons of the war. He has written a series of articles embodying his views and calling vigorously on patriotic Canadians to awake to the needs of the hour. The articles, which deal with economic, social and Imperial topics, were written for MACLEAN'S MAGAZINE and the first appears in the November issue, under the title: "The New Canada and Its Needs."

Every Mother Who Lost a Son at the Front

will read with deepest feeling Nellie McClung's wonderful story, "Men and Money," which also appears in November MACLEAN'S. Mrs. McClung wrote this story with a purpose—to show the ease with which the world forgets the contribution these mothers made. But it is also a very fine story—real, human and gripping.

"The Idle Hands at Ottawa"

By J. K. MUNRO

The recent session of the Dominion House was in many respects an idle one. There was not a great deal done, so the members had a lot of time to stir up things, and the result was some hugely interesting political situations. All of which J. K. Munro tells about in his usual unsparing and tersely humorous way.

Remarkable Features of a Remarkable Number

The November MACLEAN'S is cram full of other big features—famous writers on vital subjects and everything Canadian. Look over this list:

Baroness Orczy—The author of "The Scarlet Pimpernel," best seller of best sellers, is represented by a serial story, "His Majesty's Well Beloved."

Robert W. Service.—The great poet of the Yukon and the battle front contributes a strong poem, "The Outlaw."

Basil King.—This great novelist who lives abroad contributes an interesting discussion on "Why I Remain a Canadian."

Janey Canuck.—An article on Mrs. Murphy's experiences as the first woman magistrate in the whole of Canada.

Camilla Kenyon.—A new novelist who promises to become a great favorite, tells a humorous story of adventure, and treasure, "Spanish Doubloons."

Stephen Leacock.—A humorous sketch entitled, "My Memories and Miseries as a School Master."

"Two Men and an Idea That Grew and Grew and Grew."—By Charles Christopher Jenkins.—A sketch of two remarkable and practically unknown Western millionaires.

"A Little Bit of Chicken Feed." By Allen C. Shore.—A bright story combining love and business themes.

"The Rainbow Death."—By Madge Macbeth. An interesting detective story.

"The Search for Missing Men."—By Gertrude Arnold. An article on hospital experiences at the front by a young Canadian V.A.D.

MACLEAN'S will be Twice-A-Month

starting February 1st, next year. An important point to remember. If you want to keep up with things **nationally Canadian**, you'll have to get the MACLEAN'S Twice-A-Month habit.

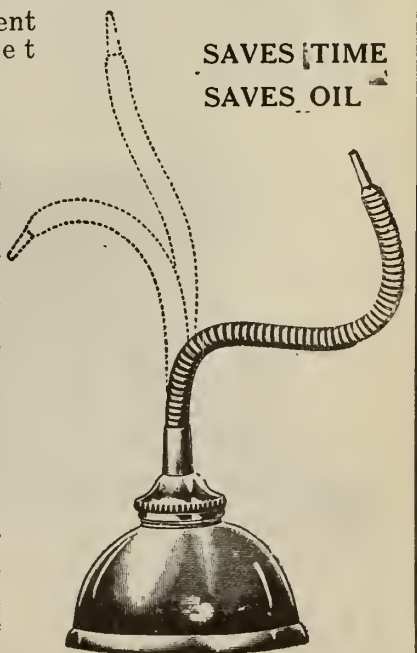
Bend the Spout

to suit the position

Every requirement satisfactorily met with

ALL-WAY OILERS

SAVES TIME
SAVES OIL



Note the flexible spout. It enables you to oil all places—many places that previously could only be reached with force pump cans with specially bent spouts.

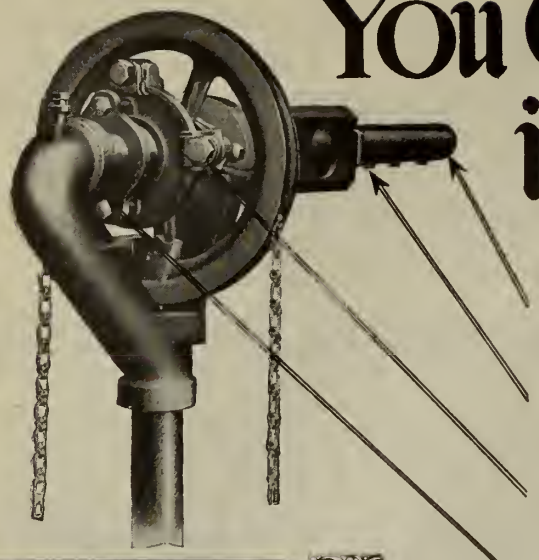
Indispensable to those who know. Will last as long as six ordinary oil cans. Saves 50% of oil bills.

Ask your dealer to show you the complete ALL-WAY line of oilers. If he cannot do so, please write to us.

THE ALL-WAY OILER MFG. COMPANY

196 KING STREET WEST - TORONTO, ONTARIO

You Can Buy Them in Confidence



WHY?

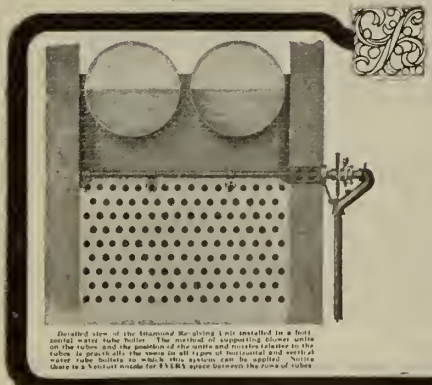
BECAUSE:

CALORIZED METAL—Blower units are constructed of metal treated by the calorizing process. This process renders the metal capable of withstanding continuous temperatures of 1800 deg. F., whereas untreated iron and steel begin to oxide rapidly at 1100 deg. F. This means that Diamond units can be placed in portions of the boiler otherwise inaccessible for cleaning.

VENTURI NOZZLES—The nozzles from which the steam issues are designed on the principle of the Venturi tube. With identical pressures steam is emitted at three times the velocity possible from a straight-walled nozzle, thus insuring the absolute maximum in cleaning efficiency.

AUTOMATIC STOPS—The range of action of the steam jets is absolutely controlled. At no time can they be directed against baffles or brick work, with consequent deterioration of the latter.

GENERAL CONSTRUCTION—Stanch, rugged, mechanically correct, Diamond Soot Blowers are noted for their dependability under all conditions of service. Mechanics, material, design have all been carried as far as they can be carried, but having been carried that far, they merge into the soot blower itself, and there the equipment stands complete, a single unit, not a list of features. Ask for Bulletin 192.



Detailed view of the Diamond Re-gining Unit installed in a bent metal water tube boiler. The method of supporting blower units on the tubes and the position of the units and nozzles relative to the tubes is practically the same in all types of horizontal and vertical water tube boilers to which this system can be applied. Notice there is a Venturi nozzle for EVERY space between the rows of tubes.

The Jeffrey Carrier
at the
UNION PACIFIC R. R.

THIS illustration shows the Union Pacific Railway Plant at Gilmore, Neb., where a 24-in. JEFFREY Improved Carrier delivers 60 tons of crushed coal per hour. The carrier also conveys ashes into a concrete bin located just inside one of the wide walls. The JEFFREY Equipment in this plant is one of the strongest links in the maintaining of its fires at a minimum cost.

The JEFFREY Carrier is completely described in our new 96-page Catalog. Interesting shop news are shown and important installations illustrated. In addition, blueprints giving all necessary general dimensions, clearness, etc., are included in the Catalog and may be used as installation drawings. Among the blueprints is a complete erection drawing of the above installation.

Write TO-DAY for your copy of our new Catalog. Ask for No. 210-4. You'll find it valuable in making layouts for Coal and Ash Handling installations.

Handle it Mechanically

Pop!
-never fails

THE reliability of Lunkenheimer Pop Safety Valves has been demonstrated through many years of satisfactory service, on all types of boilers.

Rigid tests under live steam and their careful adjustment to meet the individual service conditions, is assurance that they will efficiently perform the functions for which they are intended.

Their remarkable durability, due to correct design and high "quality" materials, is a source of economy in many boiler plants.

Users KNOW. A trial CONVINCES.

An Exchange of Money That Pays—

When you buy Victory Bonds you simply exchange one kind of money for another.

A dollar bill is Canada's promise to pay.

So are Victory Bonds.

But Victory Bonds pay 5½% interest.

Consider the security behind Victory Bonds—
Canada and all that is contained therein.

Consider the good rate of interest—5½%.
Victory Bonds pay nearly twice as much as Savings Banks.

Consider the saleability of Victory Bonds—
Their use as security for a loan—
Their prospective advancement in price—

Canada must have this money to clean up our obligations to our army and maintain the prosperity of our Country.

These are the best reasons in the world for exchanging one kind of money for another.

Every Canadian should put all his weight behind this Loan.

He should exchange every dollar possible for Victory Bonds—and every dollar he can save for the next ten months.

BUY VICTORY BONDS

Every Dollar of this Loan will be Spent in Canada

Scale in Your Boilers

Clean Tubes Mean Coal Saving

And easier firing, less ash-handling, fewer shut-downs, prevention of bagged or burned tubes, fewer repairs, and less frequent wash-outs. METLSKIN can pay for itself in a short time.

is an unprofitable boarder. Its appetite is enormous and it consumes far more than it is worth. Why not give it TWO MONTHS' NOTICE, and put an end to your loss thereafter?

THE SIXTY-DAY TEST OF METLSKIN is open to any reliable concern that is troubled with boiler-scale, pitting or corrosion. A small daily dose of METLSKIN, for a period of two months, will bring down the most tenacious scale, and absolutely convince you that A CLEAN BOILER IS NOT ONLY POSSIBLE, but EASY.

SEND A POSTCARD for the METLSKIN booklet and learn about Our Offer, Guarantee Bond, and Prices.

METLSKIN is neither "Compound" nor "Cure-all."

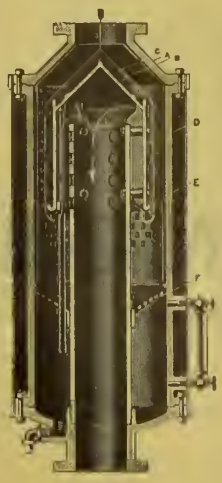
III IMPORTANT THINGS

TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

Tuxeda
SWING JOINTS

Provide one of the easiest ways to save coal

Every pound of steam that escapes through a leaky connection represents a certain amount of coal wasted. Do you know that an average leak will waste 3,400 pounds of steam a month? Investigate your flexible steam connections at once and then investigate the Tuxeda Swing Joint.

A Guaranteed Solution for Your Flexible Connection Problems

This Book Tells How

Here is a booklet that will help you to obtain actual belting economy in your plant.

It is unusually complete with descriptions, recommendations, rules and tables which will enable you to quickly determine the scientifically correct belt for any given condition.

It explains Standardization as applied to Belting, tells you how to determine the right belt for the right place on the one true economical basis—the work to be done.

Write for it—we'll be glad to send it to you.

Why Longer Tolerate

Heater Trouble and Expense?

You do not have to put up with those bothersome and expensive repairs common to ordinary heaters. You do not have to continue paying out money for fuel just to have a considerable portion of it wasted by inefficient heaters. Then, why do you? It would pay you over and over in money saved and satisfaction gained to replace your old heaters with

Alberger Heaters are furnished in capacities from 200 to 200,000 gallons per hour.

ALBERGER
MULTI-
HEAD
HEATERS

Once you do, you will never experience the cost and trouble of repairing internal defects, such as leaks, split tubes, cracked heads, etc. Nor will you ever have occasion to wait for hot water. We would like to explain fully. **May we?**

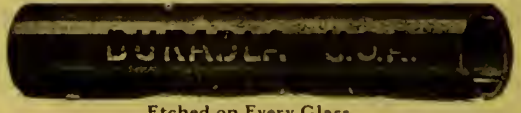
DURABLA
TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY



Etched on Every Glass

DURABLA HIGH PRESSURE GAUGE GLASS

The method of determining the fact that DURABLA American made high pressure gauge glass possessed the elastic properties necessary to withstand sudden and radical changes of temperature was explained in detail last week.
DURABLA U.S.A. glass which had passed the severe change of temperature test was next subjected to live steam to determine whether it would remain clear. After ninety-six (96) hours in a steam digester in which live steam was constantly passing through the glass at a pressure of one hundred (100) pounds, no erosion could be detected, and the glass was as clear as when first applied.
DURABLA U.S.A. gauge glasses are now ready for distribution in all standard sizes and are sold under the DURABLA guarantee.

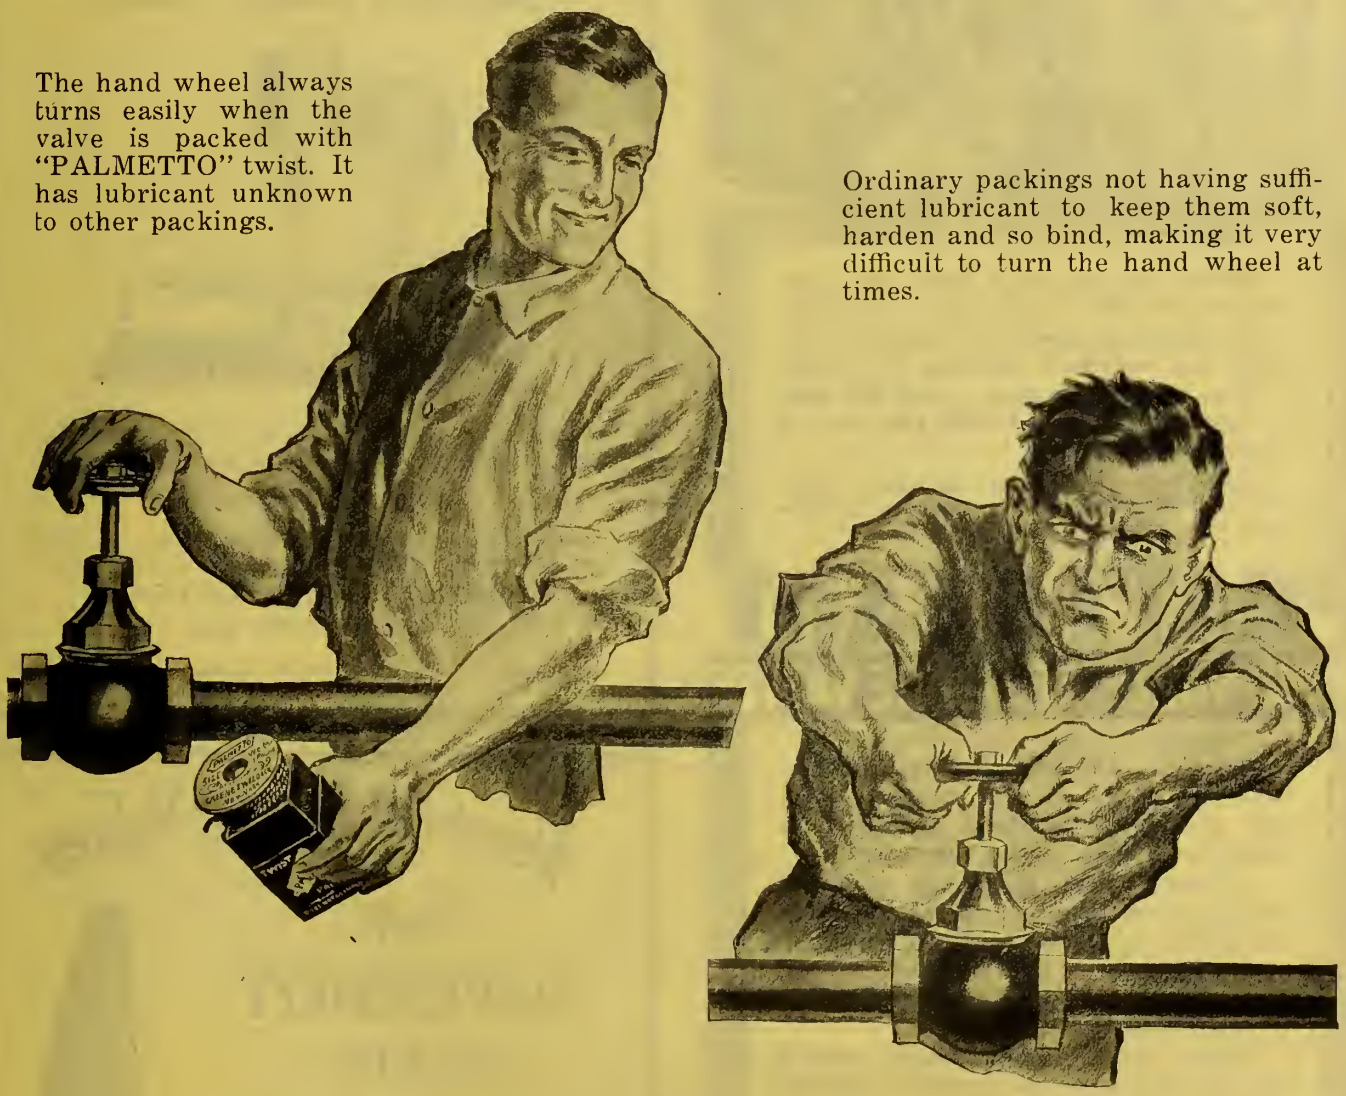
STOP AND CONSIDER

why the hand wheel of a globe valve is so often hard to turn. It's because the packing has not sufficient lubricant to prevent its leaking.

The hand wheel always turns easily when the valve is packed with "PALMETTO" twist. It has lubricant unknown to other packings.

Ordinary packings not having sufficient lubricant to keep them soft, harden and so bind, making it very difficult to turn the hand wheel at times.



TRADE MARK

"PALMETTO" TWIST PACKING

REG. U.S PAT. OFFICE

is made to give long satisfactory service in globe and other small valves.
The materials of which it is made are heat resisting and perfect lubrication of each single strand prevents hardening.

Any size valve may be packed from one spool by unstranding.

CANADIAN
FAIRBANKS-MORSE
EVERYTHING MECHANICAL

When the seat of a Pratt & Cady Renewable Seat Gate Valve becomes worn, you can insert new bronze seat rings in a very few minutes. The valve is then as good as new. And the cost is nominal compared with the cost of a new valve.

Anyone with a wrench can easily make this change. There is nothing to become loose or drop out and obstruct the line.

PRATT & CADY
RENEWABLE SEAT GATE VALVES

The gate in these valves is a double-faced, wedged-shaped casting with side grooves, by means of which it slides on guides in the valve body.

Guides in the body are of equal thickness and the wedge can be taken out of the valve and replaced with the opposite faces in contact and give an accurate fit. In making repairs this is important.

These valves being double seated can be used with the pressure applied at either end.

Gauges are used in machining all parts to insure accuracy and interchangeability.

Made of bronze and iron in all sizes. Adapted for steam, air, oil, gas or water service.

Large stock at branches insures prompt service.

May we send you our Catalog?

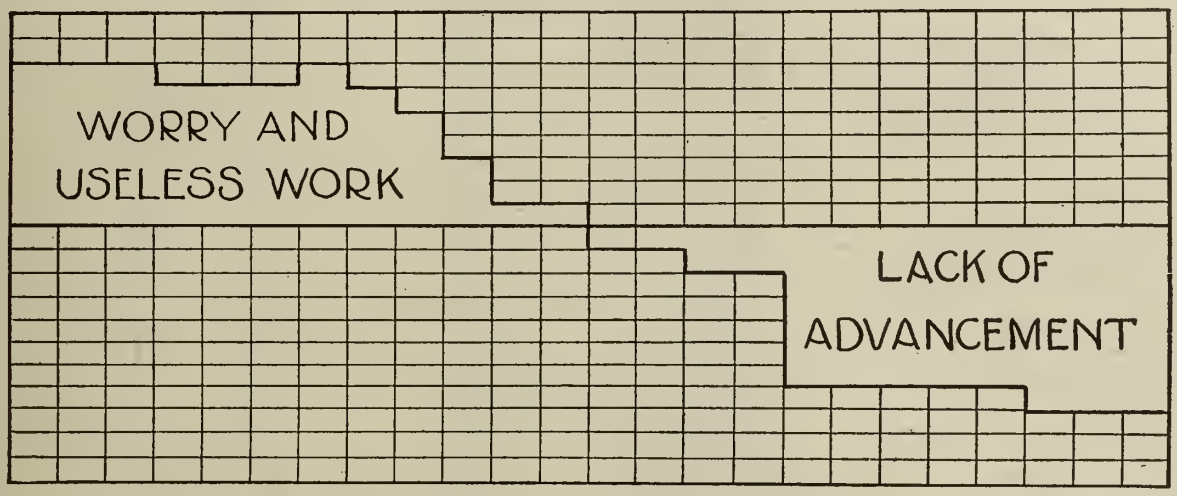
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

CUT THE CHEAPEST WAY
Use the right Starrett blade and remember the importance of gradually increasing the weight or pressure as the number of cuts increase. As soon as the blade is "eased" into the cut put on enough weight to keep the blade cutting at its maximum efficiency. The safe way is to follow the Starrett Chart. Send for Catalog and Chart "CD."

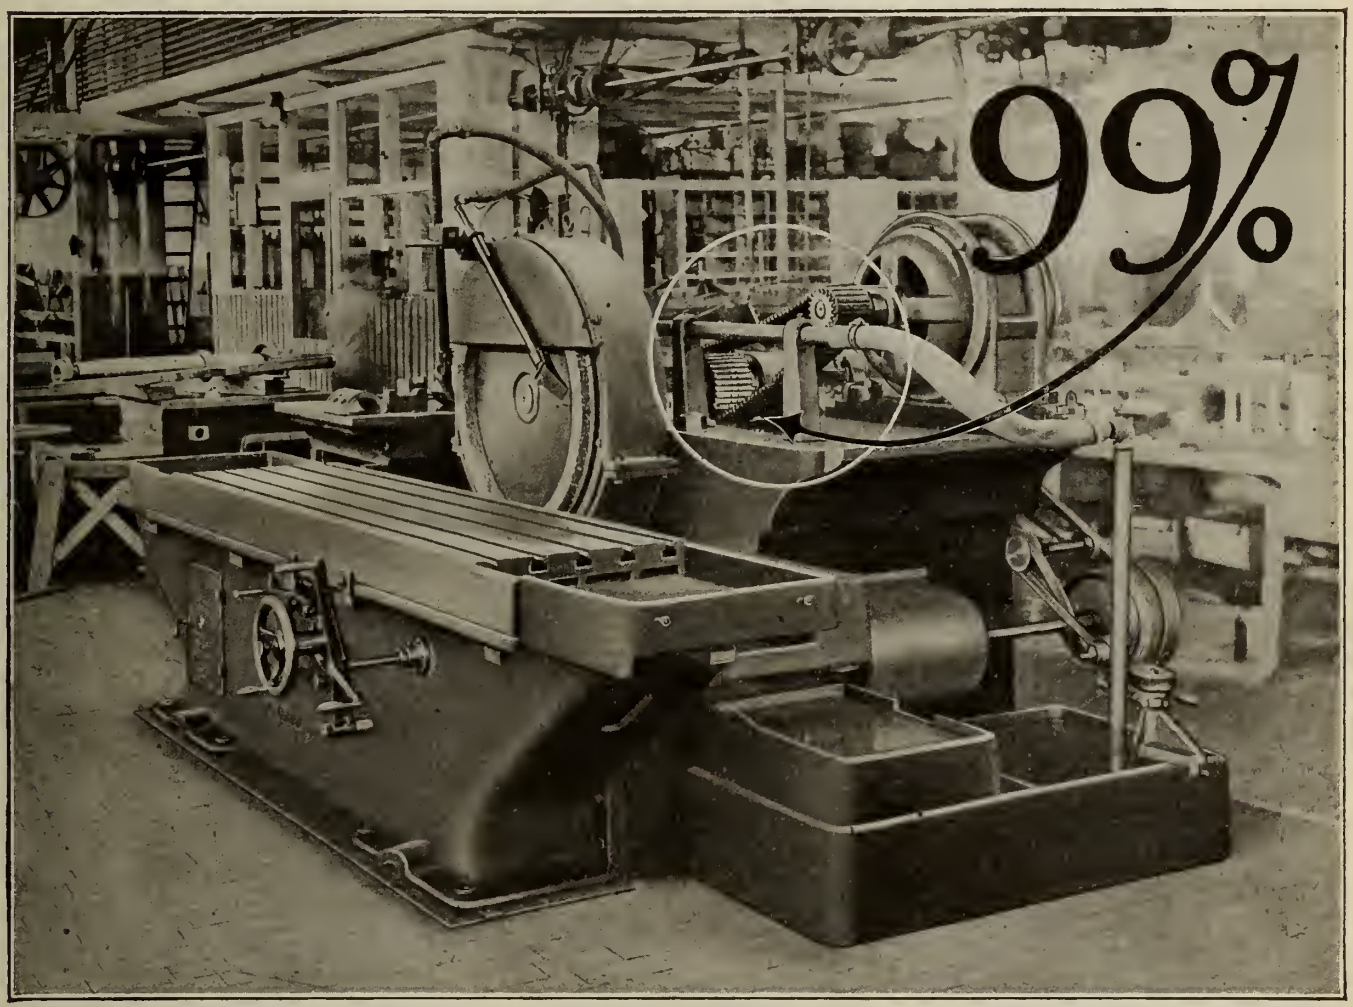
The Drive of Efficiency — *The Drive of Durability*

MORSE CHAINS

THE MORSE ROCKER JOINT

Positive as Gears — *Flexible as a Belt*

Longer Life



Full Power **Heavy Duty Face Grinder Drive** **Heavy Service**

DIAMOND MACHINE CO., Providence, R.I.

Power for your machine—Efficiency in your Production
Durability in your transmission—Confidence in your Cost

Reach their highest effectiveness when "MORSE" Rocker Joint Silent Chain Drive transmit the power. There is only one steel belt that since the beginning of its use has made good—and held itself supreme through years of hard service and that one is MORSE.

In these strenuous times early specifications of requirements are very desirable to insure prompt deliveries.

Bring your transmission problems to MORSE Engineers.
They are men of wide experience. Let them help you plan your drives.

MORSE CHAIN CO., Largest Manufacturers of silent chains in the world **ITHACA, N. Y.**

MORSE ENGINEERING SERVICE — ASSISTANCE WITHOUT OBLIGATION

DEFENDER

DUPLEX DRAFT GAUGE

The Peer of Them All

Price $20.00

They read: Draft over the fire. Draft at the last pass of the Boiler and the differential through the Boiler.

THE FIREMEN CONTROL the fires by the readings on the Gauge. It shows every condition of the Fires and Boilers, except Flue Gas Temperatures and the Defender Flue Gas Pyrometers show the Flue Gas Temperatures. Also see the Defender CO_2 Analysers, put up in permanent case so as to take a reading for CO_2 in less than one minute's time. Write for Bulletin No. 100.

Defender Catalogue No. 11 shows the largest assortment of Combustion appliances, efficiency instruments and damper regulators made. We can help you save fuel.

DEFENDER AUTOMATIC REGULATOR CO., 709 Pine St., ST. LOUIS, MO.

Does Your Storage System Save Oil?

If you have never studied the question of storing, distributing and using oils, you will be surprised to know the enormous losses that occur daily wherever oils are handled by inefficient methods. Losses that could easily be prevented by use of

BOWSER OIL STORAGE SYSTEMS

Such Conditions Are Wasteful, Dangerous, Unnecessary

Save All the Oil!

Store oils in leakproof, dirt-proof tanks. There is no loss of oils from any source, no loss of quality. Labor in handling is cut to the absolute minimum.

Write for literature describing equipment for your needs.

Reducing Valves

NON-EQUALIZING
EXTREMELY SENSITIVE
EQUALLY SUITABLE FOR STEAM OR AIR
REDUCING VALVE PERFECTION

The Non-Equalizing feature of the J.M.T. Standard Reducing Valves will surely commend itself to you. A guarantee of a perfectly uniform and dependable service, is remarkably sensitive for control, and is really a long step in advance of Reducing Valve construction.

Made in bronze, ½ in. to 2 in., and iron body, bronze mounted, 2½ in. to 6 in., for various steam ranges between ½ lb. and 300 lbs.

The J.M.T. Improved Automatic Injector

An Injector having a full forty pounds more field than anything heretofore produced and giving absolute service under varying conditions.

A culmination of valuable experience in design and the making of Injectors, likewise increasing the use for Injectors. Will operate successfully on 20 lbs. low to 220 lbs. high steam pressure, from 4 to 400 horse-power, and made in sizes from ⅜-in. to 2-in.

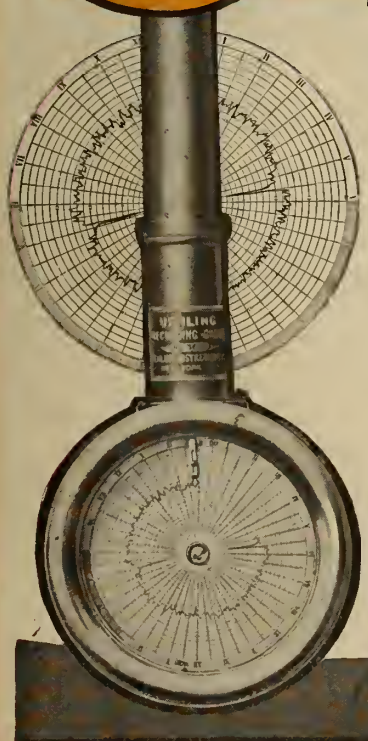
Vol. XII.—No. 19. Publication Office, Toronto—November 20, 1919 Published Semi-Monthly $1.00 per Year

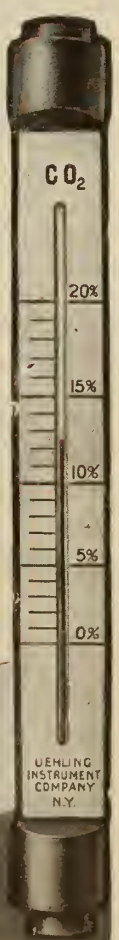
HIGH FUEL ECONOMY

CAN BE MAINTAINED WITH THE

CO_2 Uehling Recorder



The percentage of CO_2 tells you just how much heat you are losing due to excessive or insufficient draft, air infiltration through faulty boiler settings, incorrect firing, etc., enabling you to greatly reduce the tremendous fuel waste.



UEHLING EQUIPMENT

provides a continuous (not intermittent) CO_2 record. See Chart.

The recorder may be placed at almost any distance from the boiler room—for example, in the chief engineer's or superintendent's office.

Auxiliary CO_2 Indicator at boiler front helps the fireman and holds him responsible for the records produced.

Underlying principles are simple. No mussy chemical solutions required.

Uehling CO_2 Recording Equipment is made up in various styles and combinations to meet all power conditions.

Send for our Booklet entitled: "Combustion and the Cost of Power"

UEHLING INSTRUMENT CO.

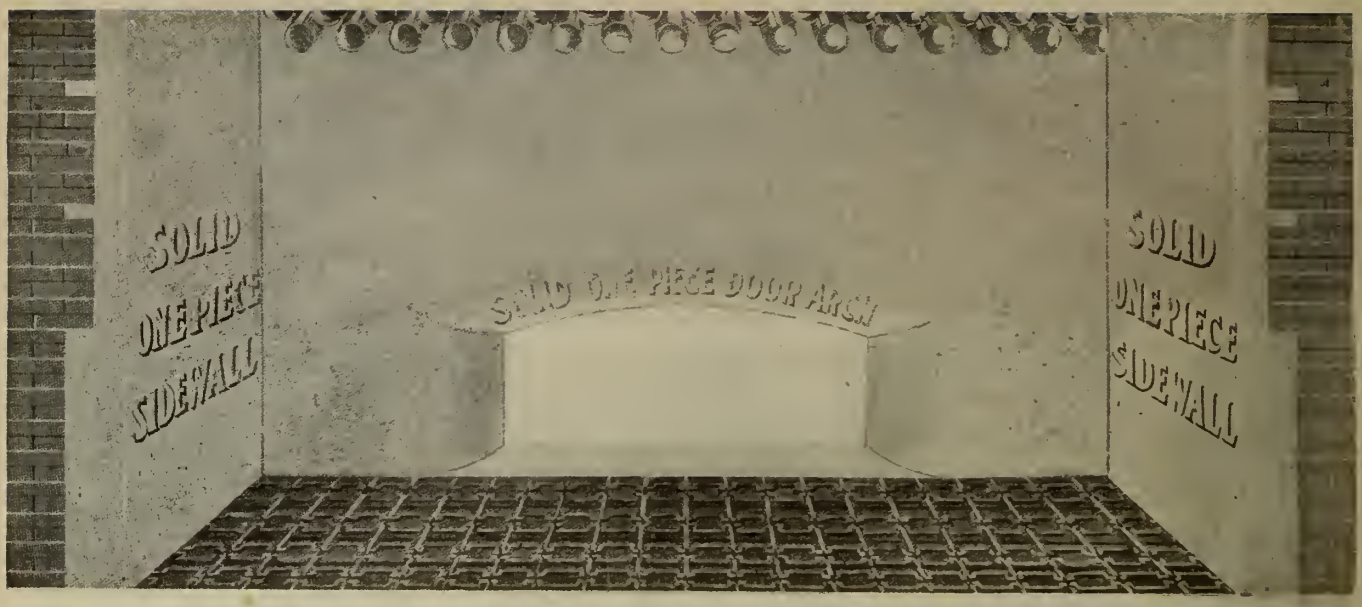
NEW YORK



Sketch above represents the fire box of a water tube boiler lined with PYRO-PUTTY.

If you could make your furnace lining with ONE BRICK—think—

OF THE NUMEROUS JOINTS YOU WOULD SAVE AND THE AIR AND HEAT LEAKS THAT WOULD BE ELIMINATED

PYRO TRADE MARK REG U.S. PAT. OFF. **PUTTY**

FIRE BRICK IN PUTTY FORM

The World's Best Furnace Lining Material

MAKES A DURABLE ONE-PIECE FURNACE LINING

PYRO-PUTTY comes to you in a stiff, moist, pliable, "ready-to-use" condition. You simply pound it on with a mallet and smooth it off with a trowel and you have a furnace lining that will outlast a Standard Fire Brick lining several times.

Use PYRO-PUTTY to make repairs in your fire brick furnace lining

Unskilled labor can make repairs in less time and less expense than is possible with standard fire bricks. Simply clean out the breaks in the walls, pound in PYRO-PUTTY with a mallet, smooth it off with a trowel and you'll have a patch that will outwear the rest of the furnace lining.

"A few barrels of Pyro-Putty should be part of the emergency equipment of every steam power plant"

ORDER A FEW BARRELS OF PYRO-PUTTY NOW

PYRO-PUTTY is put up in 700-lb. barrels, a barrel being equivalent to 100 standard fire brick.

Write to-day for further information and prices

"Belting trouble ends where D.K. McLaren's Belting begins"

Save Coal!

DON'T WASTE BY BELT SLIPPAGE
WHAT YOU SAVE BY ECONOMIC FIRING

Belt slippage and replacement are reduced to a minimum by the use of

D. K. McLAREN'S

Genuine British Oak Tanned

Leather Belting

A leather belt will transmit 25% more power than the same sized belt of other material. Figure what this cut in coal consumption means under the present high prices and scarcity. "D. K. McLaren's **Leather** Belting" is second to none in quality and service.

A "D. K. McLaren's Leather Belt" will not only cut your belting replacement cost, but will save your coal. When the belting has become worn after long, hard service on the main drive it can be recut and used on lighter drives.

"D. K. McLaren's Leather Belting" is made from the backs of selected hides, tanned by the British Oak process and sold on a service basis.

D. K. McLaren's Leather Belting comes through the repeat order acid test with flying colors.

STRENGTH—GOODNESS—QUALITY

Etched on Every Glass

DURABLA HIGH PRESSURE GAUGE GLASS

In previous issues severe tests have been detailed in proof of the fact that DURABLA American made high-pressure gauge glass possesses the elasticity necessary to withstand sudden and radical changes of temperature, and, furthermore, that it will remain clear.

It was considered desirable next to know what the strength of DURABLA U.S.A. glass would measure after having been subjected to the strain of the tests already mentioned. Unusually high tensile strength was proved by the fact that the glass remained unbroken after hydraulic pressure of over two thousand (2,000) pounds per square inch had been applied for two minutes.

DURABLA U. S. A. gauge glasses are now ready for distribution in all standard sizes and are sold under the DURABLA guarantee.

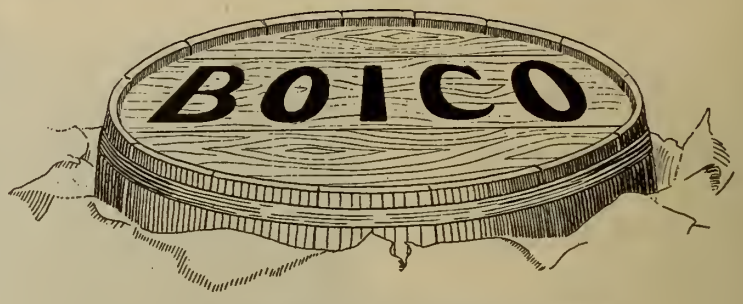
South Norwalk, Conn.

ANY·CAPACITY ANY·PRESSURE

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.



Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Hose as modern as the Cord Tire

Go back to the days before Goodyear undertook to produce better hose, and you will find that rubber hose was built in much the same way that most hose is to-day.

An old-fashioned product. Good enough for those times, perhaps, but inadequate to meet modern standards of efficiency.

Goodyear opened a new era in the industry. Goodyear disregarded tradition. Goodyear's engineers started from the ground up to build hose of modern efficiency to meet modern needs.

The inevitable result of such methods was the development of better materials and improved hose construction.

Old ideas and old methods were forgotten. Goodyear Hose was built as if hose had never been built before. Modern industry's hose needs was the standard built to.

Is it any wonder, then, that the quality of Goodyear Industrial Hose dominates as does the quality of Goodyear Cord Tires?

Is it any wonder that Goodyear Hose gives longer, more satisfactory service and costs less in the end?

Goodyear builds a particular hose for every industrial purpose—water, steam, pneumatic tool, air drill, railway, fire, suction, and so on.

Let a man trained by Goodyear study your hose problem. Phone, wire or write the nearest branch.

Halifax, St. John, Quebec, Montreal, Ottawa, Toronto, Hamilton, London, Winnipeg, Regina, Calgary, Edmonton, Vancouver.

GOODYEAR
MADE IN CANADA

INDUSTRIAL HOSE

Why you get

better service from LUNKENHEIMER "VICTOR" GATE VALVES

THE disc is a solid wedge, seating on rings which are threaded into the body in exact alignment with the disc faces; the disc is guided by ribs cast in the body, and travels to practically a closed position before coming in contact with the seatring faces. "Dragging" of the disc across the seatring faces is thereby eliminated, preventing the wear so prevalent in valves employing loose parts.

When wide open the top of the disc seats directly beneath the stuffing box, relieves the packing from pressure and permits repacking while pressure is on.

The gasket between the body and bonnet flanges is an exclusive Lunkenheimer feature. It consists of a seamless copper wire partly embedded in a groove in the body flange; will not blow out and is practically indestructible.

Bearings are bronze bushed and all parts, including the seatrings, are renewable.

Inside Screw Stationary Stem and Outside Screw and Yoke Rising Stem types for working steam pressures up to 350 pounds.

Installing Lunkenheimer "Victor" Gate Valves means permanence and satisfactory service.

Greater Power at Smaller Cost

REDUCE the friction load in your plant and get maximum power from every ton of fuel. Reduced friction also lengthens the life of machinery and adds to profit by reducing repairs and replacements and by a greater continuity of production.

Bigger and more dependable output from power-generating and power-using machinery is largely a matter of lubrication—*correct* lubrication, and *correct lubrication means good lubricants and the right one for each lubrication need.* Even lubricants of highest quality, like Imperial Lubricants, will not give the desired results unless they are properly applied.

Imperial Lubricants are right. They are carefully formulated from the best crudes. There is the *right* lubricant for the correct lubrication of every part and every machine under every service condition.

There are none better at any price. The use of Imperial Lubricants will make and keep your machinery efficient and capable of delivering maximum power at least cost per h. p. hour.

Consultation with Imperial Lubrication Engineers is yours for the asking. They will gladly study your lubrication problems and submit recommendations. Write to 56 Church Street, Toronto, or any of our branches.

Burn Low Grade Coal CUT FUEL COSTS Burn Refuse

This winter high-grade coal promises to be scarcer than ever, thus higher priced. Many power plants will have to substitute low-grade fuel and to many this will mean the installation of extra boilers to supply the required steam.

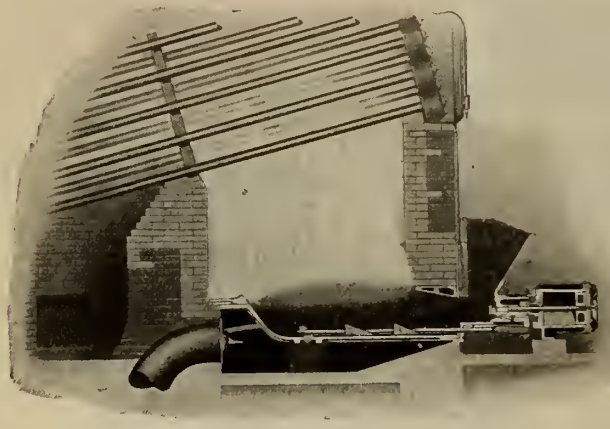
"Jones Underfeed Stokers" will burn low-grade fuel, keeping up your steam pressure and meeting your peak loads without installing extra boilers.

We furnish special stokers to burn Lignite

SMOKE ABATEMENT

The "Jones Stoker" assures proper combustion of fuel which means that the stack will be free from smoke.

The Jones simple construction means durability, no parts move in contact with the fire—no grates to burn out—no sifting of fine coal to the ash pit.



A Jones Underfeed Stoker setting under Water Tube Boiler.

The Jones Underfeed Automatic Stoker

pioneered and developed commercially the Underfeed principle of firing, which is to-day recognized as the most efficient method of stoking.

FACTS AND FIGURES ON REQUEST.

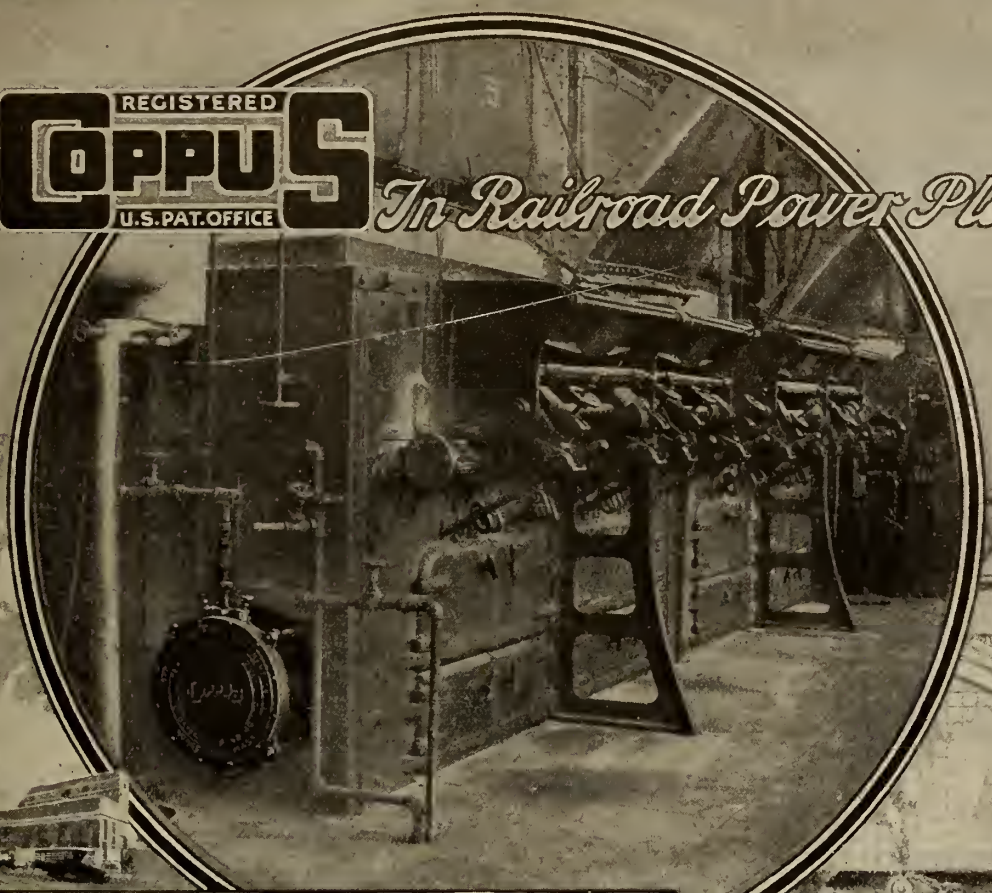
REGISTERED COPPUS U.S.PAT.OFFICE

In Railroad Power Plants



Railroads are sticklers for efficiency. Equipment approved by them must produce results — save money — earn dividends. The fact that the Central Railroad of New Jersey operates twenty-six COPPUS Turbo Blowers in their great shops at Jersey City —proves that these blowers **pay.**

Every one of this big battery of blowers—one of which is shown above—has cut coal costs—reduced labor charges—and saved dollars. In this power plant—as in thousands of others—COPPUS Blowers keep up steady steam pressure—prevent clinkering—meet peak loads quickly—and burn cheap fuel.

COPPUS Blowers **pay** a profit to the Central Railroad of New Jersey. They can do as much for you. Why not put them on the job? Catalog H-16 will show you how

Jenkins Bros. Valves

They Stay Tight

When the power house superintendent makes an inspection of the pipe lines he tests the valve bearing the Jenkins Bros. Diamond trade mark with a smile of confidence. He knows from experience, that above all things it can be depended upon to STAY TIGHT. Only valves of highly scientific design and quality construction can be depended upon to stay tight under severe conditions — Jenkins Bros.' Valves are made of first-class material by workmen who know Valve requirements.

Furnished in brass or iron body, in globe, angle, cross, check, Y or blow-off, hose whistle and other patterns.

POWER HOUSE

Established 1907 Published Semi-monthly

The Hydro-Electric Plant at Keokuk, Ia.

The Mississippi River, While Flowing Through Level Country, Has Considerable Possibilities for Power Development Owing to the Enormous Volume of Its Flow. 150,000 H.P. is Generated at the Plant Described Below

THE accompanying illustrations, Figs. 1 and 2, show the Keokuk 150,000 h.p. Hydro-Electric plant from the Iowa side of the Mississippi River and the down-stream side of the dam, while in drawings, Figs. 3 and 4, and photograph, Fig. 5, may be seen the four intakes converging into the scroll chamber around the 10,000 h.p. turbine and the 7,500 kv.a. electrical generators in the power house of the Mississippi River Power Company, which has a total capacity of over 15,000 h.p.

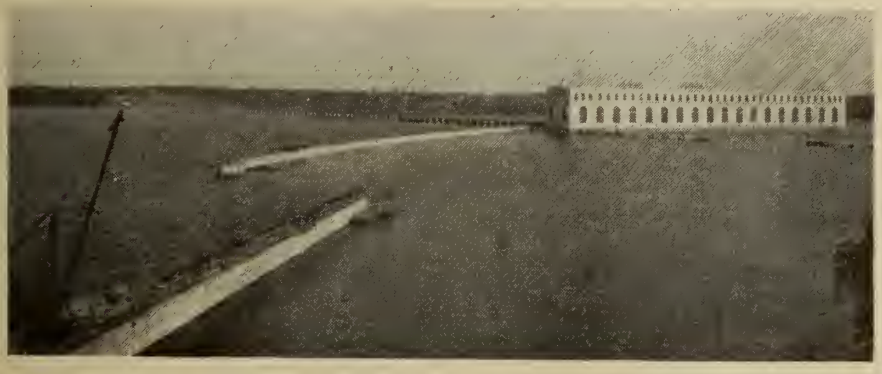

FIG. 1—POWER HOUSE AND DAM.

It will be seen from Figs. 1 and 2 that the throwing a dam across the Mississippi River, and flinging down into the centre of the great Mississippi Valley a Hydro-Electric development as large as this at Keokuk, has involved many things, direct and indirect, which are of great interest. The engineering, as it always is, was but the means to the end. The ultimate object was the production of electric current to be used for the benefit of mankind and especially of the inhabitants of the Mississippi Valley. Pains have been taken to make the effects of this water-power development, exerted through the electric generators and transmission lines, as plain as possible to everybody in the treatment of the economies. Giving this section of the country so large a quantity of the most economical power possible to use in factories has marked far-reaching effects for good upon the whole population of the country.

The object has been the development of a large quantity of water power in the centre of the Mississippi Valley, convenient to many raw materials and a large consuming population. The output is electric current chiefly for power and manufacturing. The location of the plant is in the Mississippi River between Keokuk, Iowa, and Hamilton, Ill. The stockholders live in Keokuk, Boston, New England, the East, Canada, England, Germany, France and Belgium. Chief Engineer Hugh L. Cooper has charge of the great power station.

The dam, power house, lock, dry dock, sea-wall and ice fender are all one concrete monolith, with a total linear measurement of 13,185 feet, or two-and-a-half miles. The dam has a length of 4,278 feet, plus east abutment 290 feet and west abutment 81 feet, a total of 4,649 feet, or 88-hundredths of a mile.

The dam has a width of 29 feet at top and 42 feet at bottom, the height of structure being 53 feet. It is composed of 119 arched spans, with piers 6 feet thick and span 30 feet inside. The spillway sections each measure 30 feet long and 32 feet high. The steel gates on top of spillways are 11 by 32 feet. The up-stream face is vertical and the down-stream face of spillways an ogee curve, while the dam is keyed into the limestone bottom of the river about 5 feet.

The power house has a length of 1,718 feet and a width of 132 feet 10 inches; the total height was 177 feet 6 inches, and the substructure is of monolithic concrete, with walls of reinforced concrete and steel roof trusses. It has four floors, the first containing generators and accessories, and the others containing the oil switches and electric accessories. The substructure is 70 feet high to generator floor and 78 feet high to transformer floor. The superstructure is 107 feet 6 inches from the generator floor to the pinnacle.

The installation was designed for thirty units with turbine and generator on same vertical shaft with four auxiliaries added, the first installation being fifteen power units and two auxiliaries. The turbine is of the Francois type, of special design, with a capacity of 10,000 h.p. and an overload capacity of 13,500 h.p. The efficiency is 88 per cent, at 57.7 revolutions per minute.

The diameter at buckets is 10 feet 2 inches, and the lubrication of thrust bearing is by forced pressure oil. The single thrust bearing is set above the water and carries rotating parts weighing 550,000 pounds. The turbine is direct-connected with the generator, on

FIG. 2—DOWN STREAM SIDE OF DAM.

a vertical shaft 25 inches in diameter. Sixteen buckets are on hub, the rating based on a head of 32 feet. The regulation is by guide vanes at the inner circle of the scroll chamber, actuated through a system of levers by fly-balls acting on an oil relay.

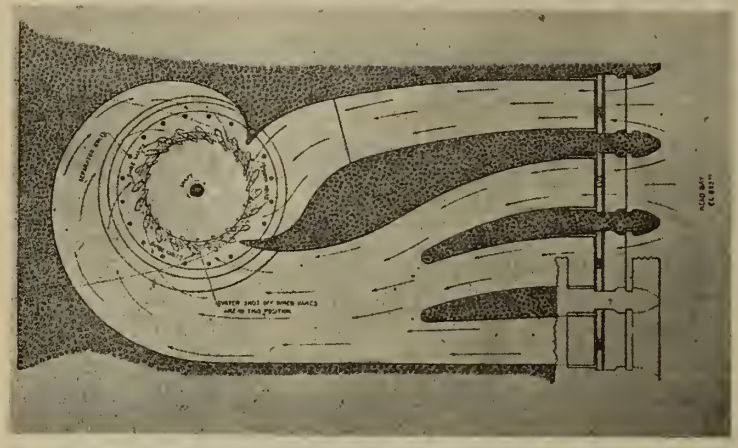

FIG. 3—FOUR INTAKES CONVERGE TO FORM THE SCROLL CHAMBER.

It will be seen in drawing, Fig. 3, that for each unit there are four intakes, converging into a scroll chamber 39 feet in diameter, with spiral floor, the whole so shaped that the water strikes every point on the circumference of the turbine with equal velocity and impulse. The draft-tubes are below the turbines, vertical, and 18 feet in diameter at the top. At the bottom, horizontal and of oblong shape, 22 feet 8 inches in vertical diameter, and 40 feet 2 inches in horizontal diameter. The bottom of the draft-tubes and bottom of the tail-race are set 25 feet below the bottom of the river. The tail-race is excavated parallel with the east wall of the power house and down to the railroad bridge.

Each electric generator has a capacity of 7,500 kilowatts. The current generated is alternating, 25 cycle, three-phase, generated at 11,000 volts, and stepped up to 110,000 volts for transmission. The field revolves at a speed of 57.7 r.p.m., and is excited by auxiliary units through a motor-generator set for each one. The diameter of the generator on the floor is 31 feet 5 inches, and the diameter of the revolving field is 25 feet 5 inches, its height at centre being 11 feet 3 inches.

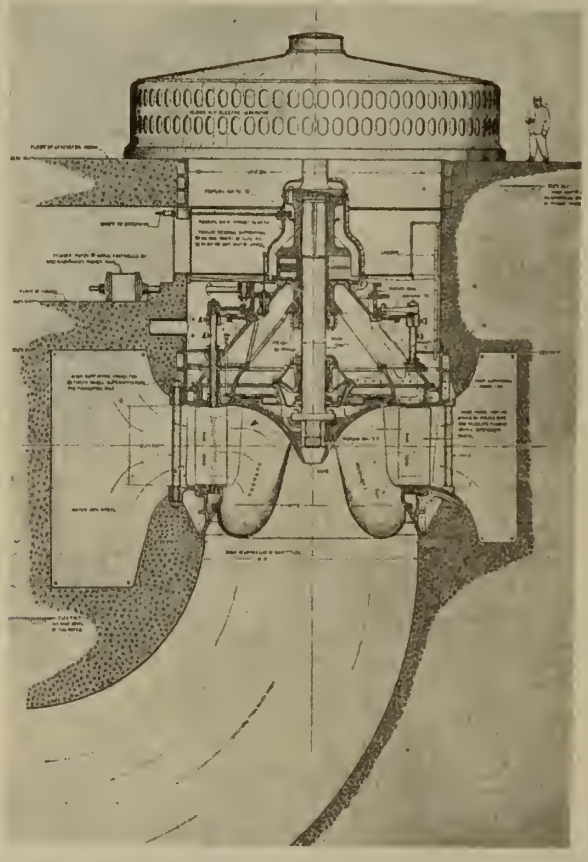

FIG. 4—DRAFT TUBE, TURBINE AND GENERATOR.

The transmission lines include one to Saint Louis, 144 miles, with a voltage of 110,000; six copper cables, five-eighths inch in diameter, each composed of 19 wires supported on steel towers set on concrete foundations in a right-of-way 100 feet wide. It crosses the Mississippi river twice and Missouri river once. The line to Burlington is 40 miles long, with voltage of 11,000, of aluminum cables on poles. Both lines are built to withstand extraordinary weather conditions and minimize accidents.

The total amount of concrete was about 650,000 cubic yards, requiring about 650,000 barrels of cement and 300,000 cubic yards of sand. The power to be developed includes a capacity at generators of over 231,500 kilowatts, and of turbines of 310,408 horsepower.

Nearly all the water-power development in the United States is on the edge of the country, from California along the Canadian border and down the Atlantic coast to Carolina, thence across Georgia and Tennessee to Alabama. This is the only very large development in the heart of the nation. This development exceeds that in any one state except three, New York, Maine and California. It is about half the total of all five companies at Niagara, on both sides of the international boundary, and it is practically all available for manufacturing. It is sold much cheaper than steam power costs, and factory sites are plentiful and being rapidly taken up.

ENGINEERING SECTION OF THE NATIONAL SAFETY COUNCIL

In accordance with the action of the annual meeting of the National Safety Council in Chicago, on October 1, the Executive Committee of the Council has approved the organization of an engineering section along the lines described below.

This plan does not contemplate a "safety engineering" section, nor does it attempt to define the term "safety engineer," which has been commonly applied to all men in responsible charge of safety work. The purpose of the new section is to bring together in closer contact the civil, mechanical, electrical, mining and chemical engineers in the council's membership, so that they may contribute more effectively towards the solution of the purely engineering problems so frequently encountered in safety work—just as the physicians among the council's membership are united in the health section.

Membership qualifications are parallel to those of the great national engineering societies, except that, for the present, associate membership (without the right to vote or hold office in the section) is open to engineers having three years experience; this will gradually be increased to six years, which is the requirement of those engineering societies

FIG. 5—INTERIOR VIEW OF POWERHOUSE SHOWING GENERATORS.

having the highest standard of membership.

The details of the plan approved by the executive committee, on the recommendation of a special committee of engineers, are as follows:

Membership

The membership of the engineering section shall be composed of individuals who are members of the National Safety council or who are employed by or affiliated with members of the council and who, in addition, have the following qualifications: Either (1) they must be members of the American Society of Civil Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Chemical Engineers, or Canadian or European societies of equal standing; or (2) they shall have had at least ten year' experience in engineering work and shall have been for at least five years in responsible charge of such work—a degree from a recognized college of engineering being accepted as equivalent to two years' experience. Persons who are members of the council, or employed by or affiliated with members of the council, may become associate members of the Engineering Section if they are either (1) associated members of the American Society of Civil Engineers or the other engineering societies abovementioned, or (2) if they have had three years of experience in engineering work, a college degree being given the same credit as above. Such associated members shall have all the rights and privileges of members except the right to vote or hold office in the Section.

Organization

The Section shall have a chairman, a vice-chairman, and a secretary, the secretary being a member of the engineering staff of the National Safety Council, and an executive committee of not more than twenty-five, including the officers, and at least one member representing each of the industrial sections of the council. Among the sub-committees of the executive committee there shall be a committee on membership, with five members, which shall pass upon all applications for membership in the section. Messrs. D. S. Beyer, J. R. Brownell, A. P. Costigane, L. A. DeBlois, G. T. Fonda, H. W. Forster, E. B. Morgan, L. R. Palmer, C. E. Pettibone, C. C. Rausch, H. A. Schultz, F. P. Sinn, T. S. Stanion, C. M Talbert, B. F. Tillson, C. P. Tolman, E. B. Tolsted and J. S. Williams are constituted a temporary Executative Committee to perfect the organization of the Section.

Functions

The functions of the Engineering Section shall be:

(1) To help to meet the technical demands of the various industrial sections and furnish them technical information as desired;

(2) To perform technical services for the council on request of the executive committee of the council, such as the development of standards or participation therein; the solution by inquiry or through research, of special engineering problems arising in safety work, and helpful co-operation with the American Engineering Staandards committee, the national engineering societies, the Bureau of Standards, the casualty department of underwriters' laboratories, etc.;

(3) To conduct one or more meetings as a part of the Annual Safety Congress, at which engineering problems shall be discussed;

(4) To conduct, if considered desirable, one or more additional sectional meetings during the year, or in different localities;

(5) To carry on such other activities as will, in the opinion of the executive committee of the National Safety Council, promote the safety movement, and the best interests of the council.

The growth of the electrical industry in Japan has been chiefly due to the development of the great water power resource of the country. The first hydroelectric enterprise in Japan was established in 1891, when the Kyoto municipality utilized the water of the drainage system from Lake Biwa to the city, a distance of about seven miles, and provided four water mills, each of 120 horsepower, and two dynamos of 80 kilowatts each. Another landmark was the opening of the first electric tramway in Japan in 1895, also at Kyoto. With the increase in generating capacity the transmission of current over long distances was undertaken with such marked success, that in November, 1914, the Inawashiro Hydro-Electric Company carried out the transmission electric power at 115,000 volts over a distance of 140 miles. Taking into account power already being used or proposed to be used, it is estimated that the total water power in Japan will reach over 8,500,000 horsepower.

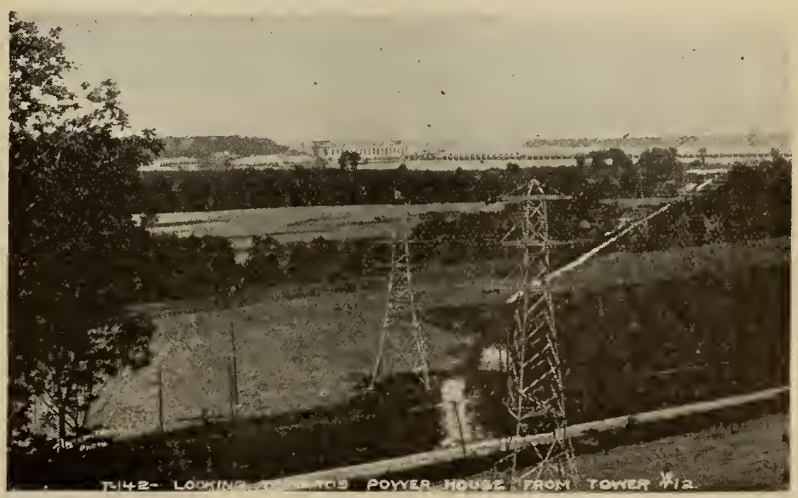

FIG. 6—TRANSMISSION LINE.

Rules for Figuring Boiler Horse-power

In View of the Coming Into Force of the Graded Certificate Act in Ontario, the Rating of Boilers is of Much Interest to the Engineer. The Following Article Gives a Resume of the Subject

By W. F. SUTHERLAND

IN connection with the grading of certificates in Ontario, the question of boiler horsepower is of much interest to the engineer and affects his interests very materially. Unlike a mechanical horsepower, brake or indicated the term boiler horsepower admits of several interpretations when speaking of performance, the term is now defined as 34.5 lbs. of water evaporated from and at 212° Fah. per hour, although at various times different figures have been adopted.

This is not taken into consideration to any great extent when speaking of the nominal rating of a boiler. The nominal rating expressed in horsepower is determined by the number of square feet of heating surface exposed to the combustion gases. Here again uniformity is not universal and various figures for the number of square feet, heating surface to the horsepower have been in use. For those interested in the Ontario regulations the figures taken in the Act may well be used.

The clause in the Act which defines horsepower is as follows:—

"B.H.P. shall mean boiler horsepower or the equivalent to the evaporation of 34 lbs. of water from and at 212° Fah., 15 square feet of heating surface for return tubular boilers, 12 square feet of heating surface for locomotive type boilers—10 square feet heating surface for water-tube boilers."

The usual rule for the determining of heating surface is to consider as heating surface, all the surfaces that are surrounded by water on one side and by flame or heated gases on the other, using the external instead of the internal diameter of the tubes for convenience in calculation; the external diameter usually being made in even inches or half inches. This method is not quite accurate since the true heating surface of a tube is that side which is exposed to the hot gases which is the inside surface in a fire-tube boiler. The resistance to the passage of heat from the hot gases on one side of a plate or tube to the water on the other, consists almost entirely of the resistance to the passage of the heat from the gases into the metal, the resistance of the metal itself and that of the wetted surfaces being practically nothing.

In finding the heating surface of vertical tubular boilers, multiply the circumference of the fire-box (in inches) by its height above the grates; multiply the combined circumference of all the tubes by their length and to these two products add the area of the lower tube sheet; from this sum subtract the area of all the tubes and divide by 144; the quotient is the number of square feet of heating surface.

Rule for finding the heating surface of horizontal tubular boilers; take all dimensions in inches. Multiply two-thirds of the circumference of the shell by its length; multiply the sum of the circumference of all the tubes by their length; to the sum of these products add two-thirds of the area of both tube-sheets; from this sum subtract twice the combined area of all the tubes; divide the remainder by 144 to obtain the result in square feet.

The heating surface in the tubes may be found by the following rule:—Multiply the number of tubes by the diameter of a tube in inches, by its length in feet, and by 0.2618.

Another rule sometimes used for determining the h.p. rating of horizontal tubular boilers is the following:—Square the diameter in feet and multiply the result by three.

It will be of interest to work out an example showing just how the heating surface and horsepower of a horizontal return tubular boiler are determined.

Take a boiler of the following dimensions, diameter 72 in., length 18 ft., 72 tubes 4 in. in diameter.

The circumference of the boiler is $72 \times 22/7 = 226$ in.

Two-thirds of the circumference multiplied by the length, also in inches—2/3 of $226 \times 18 \times 12 = 32{,}544$ sq. in.

The circumference of all the tubes is $4 \times 22/7 \times 72 = 905$ inches.

The heating surface of the tubes is accordingly $905 \times 18 \times 12 = 195{,}480$ sq. in.

Two-thirds of the area of one head less the area of the tubes is $(72 \div 2)^2 \times 22/7 - (4 \div 2)^2 \times 22/7 \times 72 = 3{,}168$ sq. in.

The net area of the two heads is, therefore, $3{,}168 \times 2 = 6{,}344$ sq. in.

The total heating surface will be $32{,}544 + 6{,}334 + 195{,}480 = 234{,}354$ sq. in. or 1,630 sq. ft.

The horsepower rating of this boiler will be $1{,}630 \div 15 = 108$.

Out of curiosity we may calculate this horsepower rating by the rule last given. The diameter of the boiler in feet is 6. Squaring this gives 36, and multiplying by 3 gives us 108 as before. This result is the same more by accident than design, for the two methods have nothing in common, and another size of boiler might give divergent results. This rule doesn't take into account the difference in length which is possible in boilers of the same diameter. Boilers of a longer length have a higher nominal rating than short ones, but the evaporative capacity is not greater in proportion for the extra length is not so effective in the absorption of heat from the gases resulting from combustion.

While the figuring out of the rating of any boiler is an easy matter it is much easier to consult a table, and for this reason one is appended giving the boiler horsepower rating of standard horizontal tubular boilers on the basis of 15 sq. ft. per boiler horsepower, which is the figure specified in the act.

BOILER HORSEPOWER RATINGS

(On the basis of 15 sq. ft. heating surface per boiler horsepower)

Size of Boiler	No. of Tubes	Heating Surface Sq. Ft.	Boiler Horsepower
36" x 10'	32-3"	305	20.3

The Principles of a New Centrifugal Pump

The Rees-Ro-Turbo Type of Pump is Herein Described, and Various Illustrations Are Given of Interesting Portions of This Class of Pump

By J. H. MOORE

BEFORE going into the construction of this type of pump, let us go back quite a few years, and see where first the idea of centrifugal pumps appeared.

Something over two hundred years ago the centrifugal pump was invented by Demesne Papin in Hess, Germany. Little seems to have been done with it in a practical way for a long period. It first appeared in this country in 1818, and was known as the Massachusetts Pump. Gradual improvements were made in its design by Andrews in 1839, Bessemer in 1845, Appolod in 1848, and Gwyne in 1851. The development was slow and until within the last ten years was not considered seriously by many engineers, except for large capacities and for extremely low heads.

No doubt the delayed development was largely due to the fact that to get the best results from a centrifugal pump, impellers should be of small diameter running at high speed, but until the advent of the electric motor and steam turbine there was no means of driving centrifugal pumps at the necessary speed except through belting of gearing with their inseparable difficulties and losses in transmission, which neutralized the advantages aimed at in the pumps. With the introduction of electric motors and steam turbines high efficiencies became possible, and for high lifts the old arrangement of impellers in series was revised and the centrifugal pump became a strong competitor of the plunger pump for conditions which used to be looked upon as only suitable for reciprocating pumps.

Perhaps the defect which has been the most difficult to overcome and which has decided the buyer in many cases against this type of pump, has been the fact that it would work at its best only at the exact head for which it was designed, the reason for this being that the blades of the impeller were shaped so as to pass a certain amount of water with the minimum frictional loss, due to cavitation; but if the head against which the centrifugal pump is working reduces, a greatly increased volume of water passes and the impeller then becomes unsuitable for the increased speed of the water through it and begins to act as a water brake, thus creating an overload on the driving machine.

These conditions were well-known and until the introduction of RoTURBo by Rees of Wolverhampton, England, in 1907, it was attempted to overcome them by designing the impeller with blades bent rearwards so as to reduce the break effect. This necessitated increase in the speed of the impeller to compensate for the slip of the water, and beyond a certain amount of recurvature the capacity of the pump is very greatly reduced and the internal friction of the impeller increased with consequent loss of head at anything but a restricted range of service.

True, turbine pumps are of such comparatively recent development that the general public and, in fact, many engineers have not been sufficiently well informed upon the subject to distinguish between a high grade turbine pump and an ordinary commercial centrifugal pump.

Venturi Pipe

What is know as the Venturi principle is embodied in a specially shaped contraction in a water pipe having an abrupt nozzle where the water enters the construction, and a gradually expanding taper piece after the water has passed the contraction. The result of this is that the water under pressure in the pipe is forced through the neck at a high speed, and in doing so it loses its pressure, in the inverse ratio to which it gains velocity, so much so that the whole pressure can be annulled in the neck if the contraction is sufficient and an actual vacuum can be created. When the water enters the expanding pipe the speed of the same is slowed down again, due to the increasing diameter, and as the speed is lost the water regains its pressure. The Venturi pipe, therefore, is a hydraulic transformer, with a double transformation, converting from pressure into velocity and the velocity back again into pressure, and without much loss.

The special shape of the Venturi pipe is because a very abrupt contraction will convert pressure into velocity, but a carefully designed expanding piece of about 10 or 12 degrees expansion is necessary to attain the second conversion, because if the expansion is abrupt the water leaves the sides and the head (instead of being regained) is lost in friction and eddies.

In the ordinary centrifugal pump with an open rim impeller, the object is to pick up the water in the eye of the pump and get up a high peripheral velocity as of the water as it leaves the impeller and convert this velocity into pressure in the expanding channels of the pump casing; a very difficult and inefficient conversion.

These expanding channels are the exact counterpart of the expanding part of a Venturi transformer, but the contracting part of the Venturi transformer was not previously used in centrifugal pumps until what is known as the Rees RoTURBo Pressure Drum replaced the ordinary impeller. The pressure drum is a water chamber of large capacity, in which, by centrifugal force, a pressure is accumulated; the water being flung against the rim by the revolution of the drum and generating a hydraulic pressure inside of the drum. The water is allowed to escape through abruptly contracted openings in the rim, precisely in the same manner as the contracting part of the Venturi pipe.

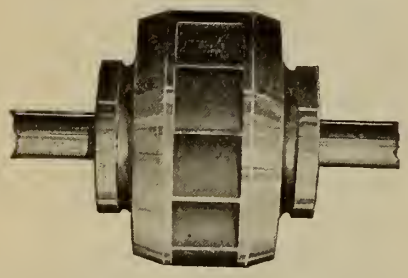
These openings, or nozzles, are pointed backward, and as the water escapes from them the jets of water have a turbine effect and give self regulation or a reduction of power when the head is reduced and a larger volume than the normal passes through the pump. The contraction of the openings is such that only 25% of the initial pressure is converted into velocity. That is to say, the water going through the nozzles at normal duty has a pressure of 75 per cent. and a velocity equivalent to 25 per cent. only. This velocity is picked up again in the expanding channels of the pump casing, so as to make the total pressure of the water being delivered from the pump equal to the 100% originally intended, but by this arrangement only 25% of the head is picked up in the expanding part, instead of the 100% as in the ordinary pump. As the expanding part of the Venturi transformer is the most difficult to design, and the efficiency of the same depends entirely upon the accurateness with which this part is designed, it will readily be seen why a pump of this type leads in the matter of efficiency.

General Principles

The design of the pump is exceedingly simple, comprising a single or a series of pressure drums (the number depending on the nature of its work), rotating inside a cast-iron casing at a moderately high speed. These revolving pressure drums are mounted on a central shaft supported in bearings. There are no moving parts in contact, except at the bearings, and the whole of the internal arrangements are such that the pump is in hydraulic balance and free from any lateral end pressure on the shaft. The main bearings are external and oil ring lubricated, and packing arrangements are exceedingly simple.

When running the water gravitates or is drawn into the eye of a revolving pressure drum where its speed is slow relative thereto, the water being carried round by the revolving partitions. A pressure is created in the revolving drum by centrifugal action of rotation, and the capacity of the chamber being large the water slowly moves towards the periphery, where there are a number of short nozzles curved in a direction op-

posite to the direction of rotation. These nozzles convert a portion of the pressure into velocity, and the water passing through them behaves as in a turbine, assisting the rotation of the revolving drum, thereby giving a self-regulating effect. The escaped water still having velocity in the direction of rotation, is passed between stationary diffusion channels which convert the remaining velocity into pressure. A considerable



SINGLE-STAGE IMPELLER.

space is left between the revolving nozzles and the stationary channels, greatly minimizing the effect of any wear and tear.

Impeller

The special feature of the pump, which (instead of being built as a flat disc runner with the main object of securing velocity of water in the expanding channels of the fixed casing), is designed in the form of a barrel or pressure chamber, the object aimed at being to secure a constant pressure inside the revolving drum or impeller, equivalent to the height of the lift. The impeller having this large capacity, the water inside as it approaches the rim becomes practically stationary relatively to the impeller, thus eliminating frictional losses and generating a pressure by centrifugal force.

Another interesting feature to note is that the highest efficiency point is when the speed of the water issuing from the impeller in a rearward direction is 50 per cent. of the peripheral speed of the impeller and this for the same reason that the Pelton wheel gives the highest efficiency when the speed of the buckets is half the speed of the water jet. In fact, the pump may be looked upon broadly as a reversed Pelton wheel in which the buckets are stationary and a series of nozzles on the rim of the impeller revolve, whilst the ordinary turbine pump with the narrow disc impeller is, of course the reversed vortex turbine.

The Effect of Self-Regulation

The self-regulating pressure chamber is the equivalent to a pump and a turbine in series, the result being that if the head varies or is reduced below the head for which the pump is designed, there is no overload possible, the turbine rim blades extracting the energy of the increased speed of the water through the impeller, which otherwise would be thrown to waste. It follows, therefore, that the margin of horse power usually allowed on the motor in the ordinary turbine pump for this emergency is unnecessary, it being absolutely impossible for the pump to overload materially the motive power so long as the speed is kept constant, regardless of the head against which the pump is working, or as in the extreme case of a pipe bursting, taking the head off the pump entirely. The value of this feature of the pump in keeping down power costs to the lowest point without the necessity of complicated arrangements for speed variation or cutting out impellers, will at once appeal to the manager or engineer.

With further reference to self-regulation and the turbine effect, it should be noted that the impeller becomes a pump and a turbine in series, with a pressure chamber between the two portions. The pump portion is, therefore, always discharging into a constant pressure, which is the ideal condition for a centrifugal pump, and the turbine is always discharging from a constant pressure, which is the ideal condition for a turbine.

The result of the combination just described is perfect self-regulation with the highest efficiency and, at any head lower than the normal duty, the power taken by the motor is prevented from rising.

Characteristics

When running under a constant speed the Rees RoTURBo Pumps are designed to deliver a certain capacity against a specified head at this speed, and will give a guaranteed efficiency at that point. If required to deliver water at a higher head (and all the following calculations are based on a constant speed), the pump will deliver against this higher head up to 115% of the designed head. The amount of water delivered will decrease as the head increases above the designed head, and the efficiency will also decrease likewise.

For instance: At 106% of the designed head the pump will deliver 83% of its capacity, and the efficiency will be 95% of its guaranteed efficiency. In a similar manner: At 108% head, delivery is 73%, efficiency 90%. At 111% head, delivery is 60%, efficiency 80%. At heads above, the capacity and efficiency are not dependable, and the characteristic curves for the pump in question will have to be referred to.

For heads lower than the designed duty, the pump is more stable. For instance: for heads from 100% of the designed head down to 82% designed head, the pump will give an efficiency of 100% of that guaranteed, and the capacity at 82% is 126% of the designed.

At 69% head, the capacity is 140% and the efficiency 93%.

At 65% head, the capacity is 145% and efficiency 90%.

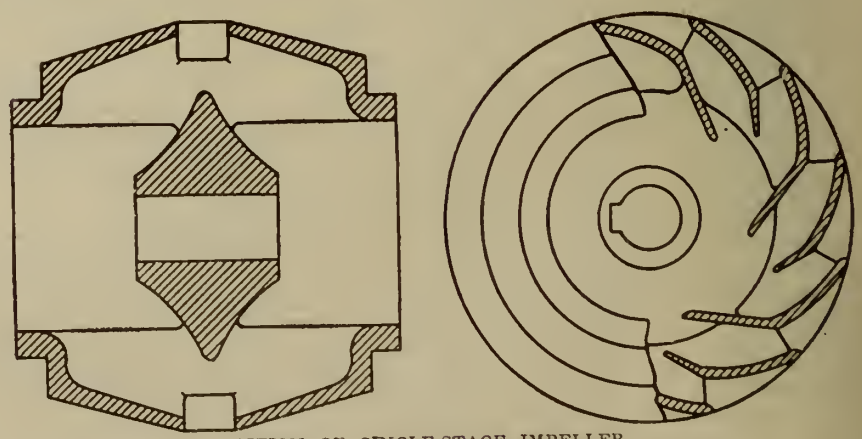
At 52% head, the capacity is 155% and efficiency 80%, etc., down to open valve or no head, at which point the pump will deliver in the neighborhood of 192% of the designed duty.

Due to this flat head and volume curve the efficiency of the pump is flat and varies over a wide range.

From the figures given you will note that it is best that the pump operate at heads lower than that for which it is designed. In fact, never, under any circumstances, would it be advisable for pump to operate under conditions where the head will be higher than that for which it was designed.

It will be noticed that the efficiency of the pump remains at the highest point until the head is reduced as low as 82% of the designed head and the capacity has increased to 125%. The pump can operate very satisfactorily down to heads as low as 40% of the designed head, and at this point the efficiency will be 60% of that guarantee, and the capacity will be approximately 160% of that for which it was designed.

A fact which should be remembered is that the volume increases directly as the speed; i.e., if the speed is doubled the volume will be doubled, and at the same time the head will vary directly as the square of the speed, and the head will be quadrupled, and likewise the power will be increased in direct proportion as the curve of the speed, or as the speed doubles the power will increase as the cube of 2 or 8.



SECTION OF SINGLE-STAGE IMPELLER.

Prof. Zowski's Report on Rees RoTURBo Pumps

The following technical report of Prof. Zowski, of the University of Michigan, sets forth clearly the principles in-

volved in the RoTURBo Pump, and will be found of interest. The accompanying curves and test cards should be of assistance in discussing the subject with consulting engineers and others.

SINGLE-STAGE DIFFUSER.

The new hydraulic principle embodied in this pump is that the impeller is used to create pressure head directly, whereas in all other centrifugal pumps the impeller imparts to the water practically speed energy only, leaving it to the diffusor to turn this speed energy into pressure head, which is always a very inefficient transformation.

A chamber of relatively large volume makes up the major part of this casing. A great volume of water is dragging along, and being exposed to the centrifugal force created by rotation is converted into a sort of accumulator which feeds the discharge nozzles and is itself fed by the suction pipe.

The speed of flow in the chamber is very small and its effect upon the pressure head which is caused by rotation is, therefore, very slight. Consequently, we may vary the discharge considerably without changing the pressure conditions in the impeller to any material extent. The variations in the discharge will only change the pressure at the entrance into the diffusor, and this produces the varying pressure differences which are, of course, necessary, if different quantities of water are to pass through the same passage area.

The fact that the speed of flow in the impeller is very small, means also that the theoretical power of the pump is practically dependent only on the pressure head created in the chamber. and therefore, equally independent of the discharge as the same.

If we now succeed in designing a pump in which also the efficiency will be independent of the discharge, then it is self-evident that the variations in the discharge will not affect much the actual power which is required to drive the pump. In this pump this condition is fulfilled for the following reasons:

1st. Because the speed of flow is very small, the hydraulic loss of the impeller will be very slight as compared with the other hydraulic losses of the whole pump, and changes of speed flow caused by varying the discharge can, therefore, not affect much the total efficiency.

2nd. The impeller nozzles act as turbine buckets, doing useful mechanical work by deviating the discharging water streams, and thus creating the S.C. force of reaction pressing against the buckets in the direction of rotation. This mechanical work increases with increasing discharge, and therefore, neutralizes to some extent the increase of hydraulic losses which takes place when the quantity discharged is increasing.

On the basis of what has been stated above, the following characteristics may, theoretically, be expected from the Rees Pump:

1st. A flat power curve with varying discharge.

2nd. A flat efficiency curve with varying discharge.

3rd. A total efficiency which must be at least as good as that of any other centrifugal pump, and which, on account of the relatively small velocities which flow through the impeller chamber, may be expected to be even better, if both are designed and built with the same amount of care and precision.

It cannot be the purpose of this report to enumerate the various instances in which this pump may be used to a greater advantage than the other centrifugal pumps, but this seems to be quite certain that the pump is ideally fitted to all services where the operation conditions are variable. Further, the peculiar construction of the impeller makes it relatively easy to use the pump as a wet compressor or as a vacuum pump, as it is a simple matter to admit the air or exhaust steam into the wide impeller chamber, and then to compress or mix it with the water in the impeller.

S. J. ZOWSKI.

On all pumps the casing is split horizontally so that the pump can be opened out and the internal parts examined by simply removing the top half of the casing.

It is very advisable to have both the branches, that is to say, the suction and discharge openings, in the bottom half of the casing, so that the top half can be removed without disturbing the branch connections. The standard arrangement is with both the suction and discharge branches horizontal and below the centre line of the pump. The suction branch can be made vertical if specially required. The horizontal suction branch is, however, preferred. The standard arrangement is with the discharge branch on the right hand side looking on the thrust end of the pump, but it is equally satisfactory to have it on the left hand side.

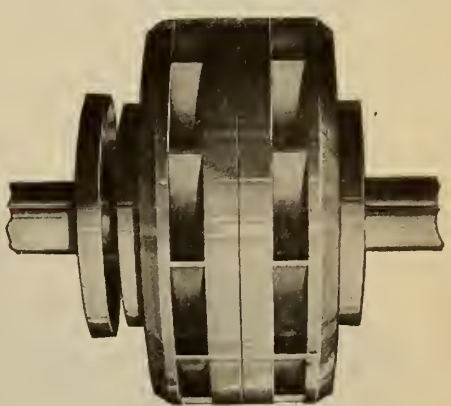
This pump may be made with either one or two main bearings. When the prime mover is supplied by another firm our practice is to fit two main bearings in all cases, but when the prime mover is supplied by ourselves, one main bearing is sufficient in the case of reciprocating engine drive and on small units with turbine drives up to moderate speeds; but in the case of high speed turbine drives (above 2200 R.P.M.) or units absorbing more than 50 H.P., two bearings should be supplied. With two main bearings a flexible coupling is used, but with only one main bearing a solid coupling is required. A brief description of the various types is given below:

MUTI-STAGE DIFFUSER.

C. W. Type

These pumps may be used for heads up to 120 feet, when the impeller is made of cast iron; double that head when it is made of bronze. It is not usually good practice to exceed 180 feet on a single-stage C. W. pump, unless it is of considerable capacity. Lubrication is by one or two oil rings, running over the shaft and dipping into a large reservoir beneath. This bracket also contains a two way ball thrust bearing, which acts as a centreing block for the impeller, keeping the nozzles in line with the diverging channel. In special cases the branches may be located at almost any position on the periphery of the casing to suit the convenience of the customer; but this should be avoided whenever possible, as it means special attention in designing and will probably entail delays in shipment.

The base plate is of cast iron, usually in one piece of the heavy boxed ribbed



MULTI-STAGE B TYPE IMPELLER.

type, extended to receive the driver. For belt drive, two pedestal bearings are furnished, thus providing a bearing on each side of the pulley. Lubrication is by ring oiling. The efficiency of this pump will range from approximately 40% on a very small pump to 80% on a large one, depending entirely on the fitness of the pump in question to the

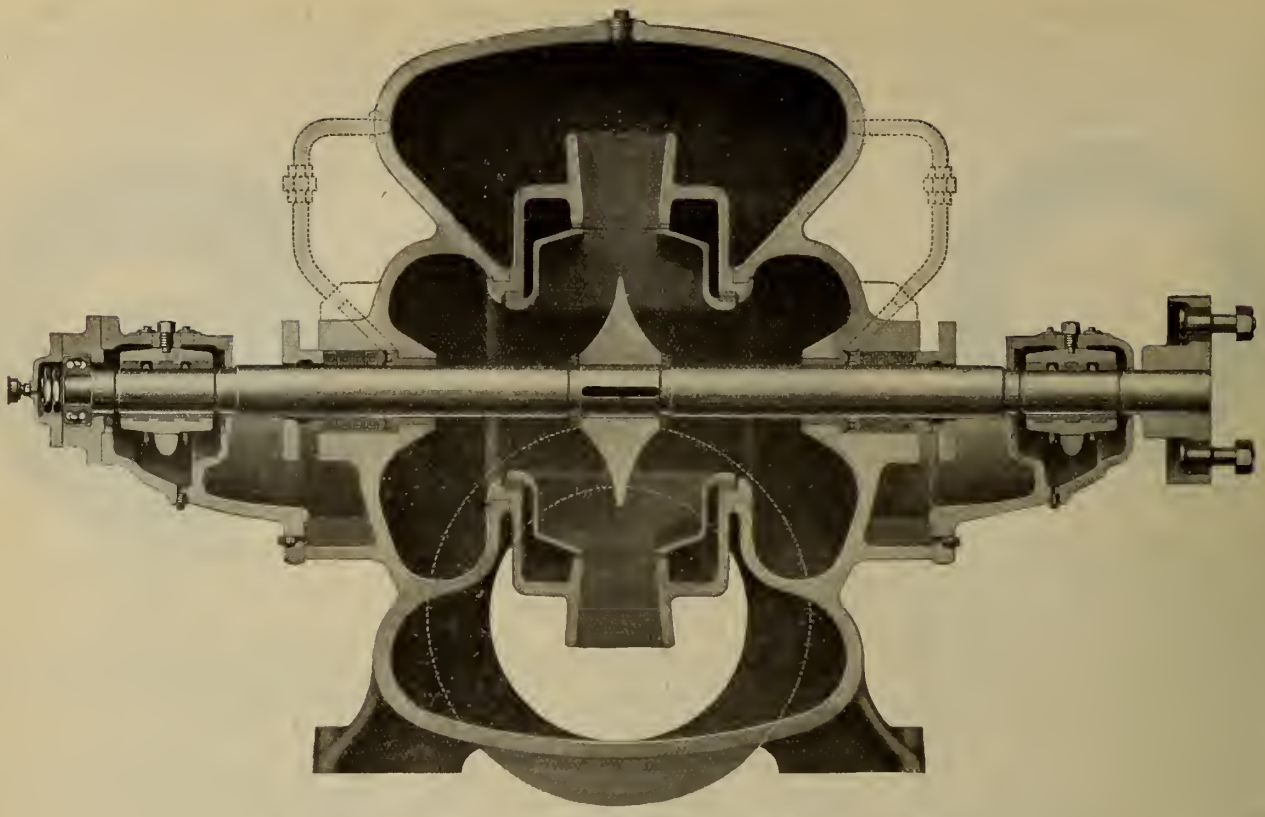


FIG. 1.—C. W. TYPE SINGLE-STAGE PATENT PRESSURE CHAMBER PUMP.—SECTIONAL VIEW.

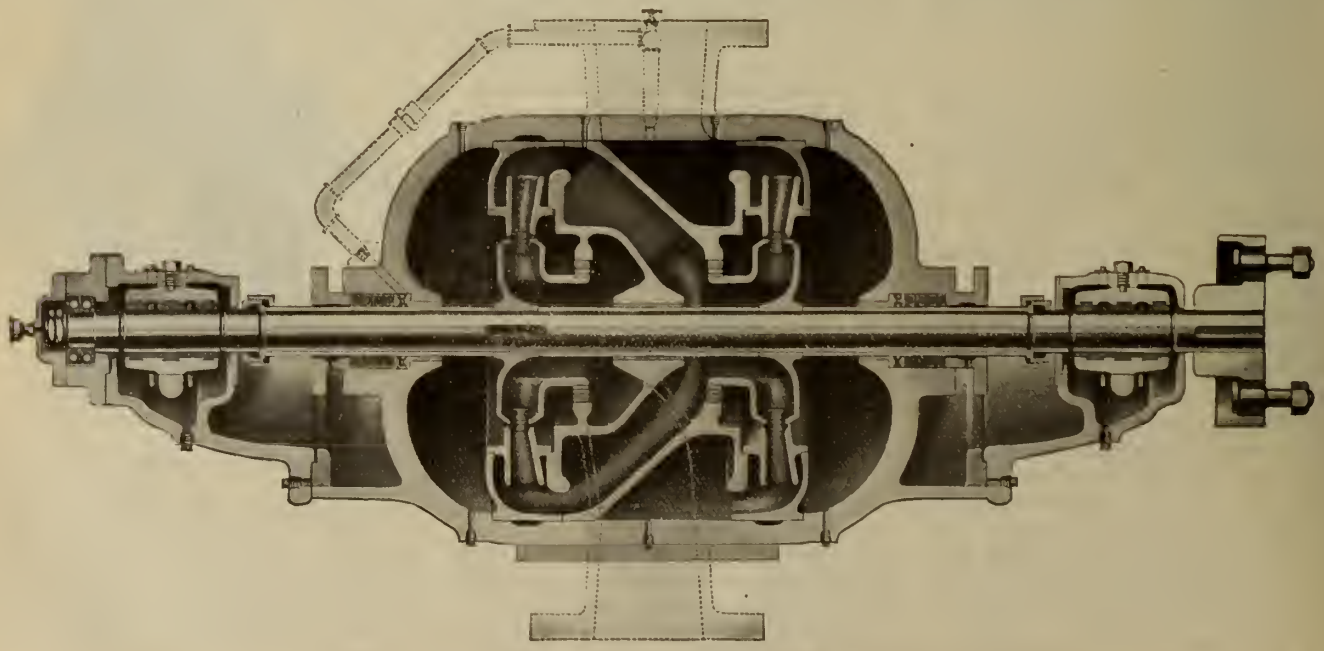
service demanded of it. Efficiencies obtainable are found for any given conditions from the efficiency charts. In practice the best efficiencies are obtained with heads varying from 40 to 140 feet.

S-2 Pump

This consists of two single stage, single impeller, single suction pumps, mounted on one shaft, and placed in one casing; in reality, this is two single stage pumps in one casing. The impeller differs from that employed in the C.W. Pump in that the water enters on one side or through one eye only, and therefore the capacity of an equivalent size S-2 impeller is only one-half that of a C.W. type of pump of the same diameter, the capacity limit of the impeller being based on the velocity of water through the eye. The impellers in these pumps, when mounted on the shaft face to face, are so arranged that water under pressure flows to the back of them, thus hydraulically balancing them with regard to end pressure. The diffusors of these pumps are two in number, and are of the straight way type similar internally to those used on the C.W Pump. What has already been said about number and type of bearings for previous pump, is also applicable to the S-2 Pump.

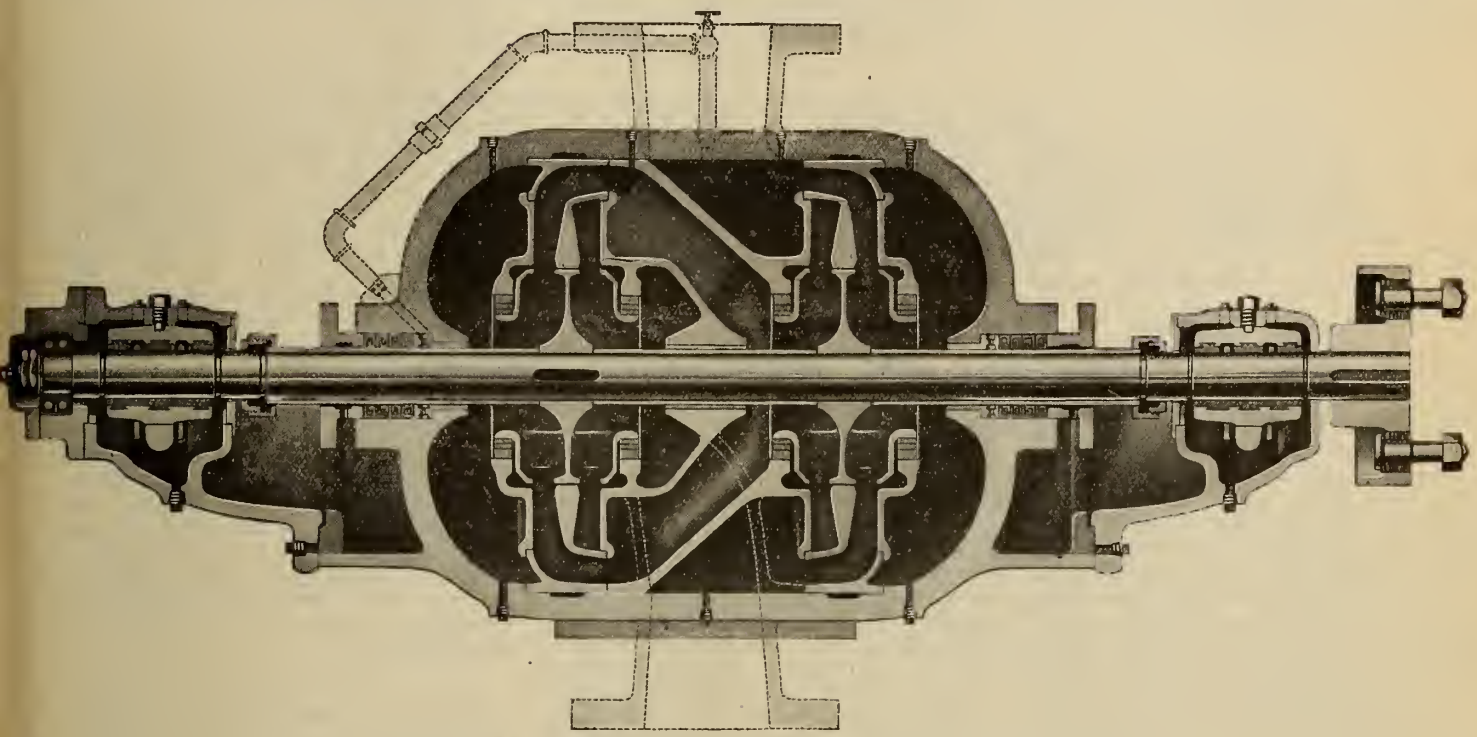
B Type Pump

This type of pump is one which is particularly well adapted for exacting service. It has many advantages over the ordinary centrifugal pump besides the special feature of the capacity chambers. It is multi-stage built in multiples of four, and not otherwise. The impeller is of the two stage type, each impeller having two stages back to back with an eye on both sides. This is a mechanical advantage in that it shortens the length



S2. TWO-STAGE PATENT PRESSURE CHAMBER PUMP.—SECTIONAL VIEW.

of the pump, and consequently the distance between bearings. The arrangement of the stages in multiples of four only, is clearly explained by reference to the method of obtaining hydraulic balance. This hydraulic balance is not only theoretically perfect but is actually so. This can easily be proven by the fact that on pumps up to 16 stages and more, a standard type of ball thrust bearing is used for the centreing block instead of the usual type of collar, water cooled marine thrust bearing, used by other pump manufacturers to take up end thrust. The end thrust experienced in RoTURBo Pumps is practically negligible. The purpose of the ball thrust used is to keep the impeller in line with the diffusors. The compactness of the pumps is further facilitated by the use of cross over diffusors. These diffusors are two combined in one, and cross the water from one stage of the pump to the next, and in this way (the water being crossed in a correct manner from one stage to the next) the pump is balanced with reference to end pressure. B types of pumps usually contain two bearings, both external to the casing, supported in brackets from each end of the pump. These are the same as those used in the other pumps, and are lubricated by means of two rings to each bearing dipping into a large reservoir of oil beneath, which has an overflow and drain. Above each stage of a B type pump is a relief or pet cock, its purpose being to relieve the entrapped air. B & S types of pumps have bronze covered shaft; the other type of pumps have steel shaft unless bronze is specified, which will be special and for which an extra charge will be made. B type pumps are used for heads from 100 to 1,600 feet. Their efficiencies are found from the efficiency charts. Given the volume and head per stage on the pump the best efficiencies are obtained with heads of from 40 to 140 feet per stage.

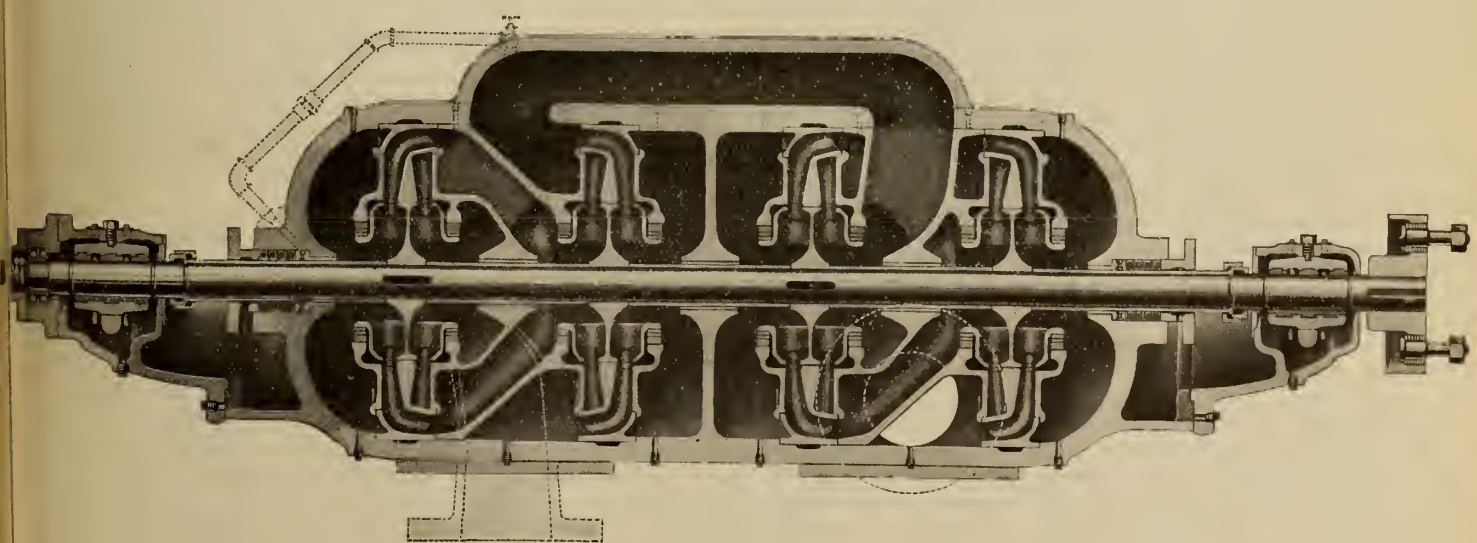


B2.—MULTI-STAGE PATENT PRESSURE CHAMBER PUMP.—SECTIONAL VIEW.

The makers of these pumps claim the following features and advantages derived from their pumps, namely that:

1. A drooping power curve, i.e., a power curve which rises not more than 10% as the volume is increased beyond the designed duty point and falls away as the volume is still further increased, thus making it impossible to impose an overload on the motor or turbine which may be used for drive.

2. High and permanent efficiency maintained over a very wide range of



B4.—EIGHT-STAGE PATENT PRESSURE CHAMBER PUMP.—SECTIONAL VIEW.

heads and volumes, i.e., a flat efficiency curve.

3. A head and volume curve which goes out to approximately 200% of the volume at the designed duty point when delivering against no head, in other words, maximum increase in volume at reduced heads. This is a great advantage for many purposes.

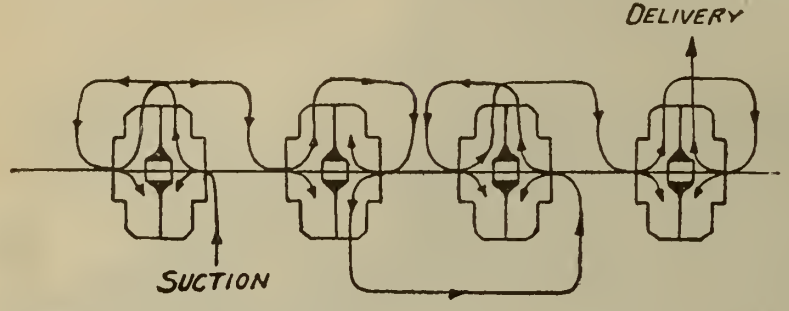


DIAGRAM SHOWING FLOW AND HYDRAULIC BALANCE OF A B4 EIGHT-STAGE PUMP.

4. Owing to the low water velocity through the impeller and stationary passages, there is almost complete freedom from wear, even when pumping gritty water. This forms a marked contrast to the ordinary centrifugal pump, where facilities have to be provided for the renewal of blade tips and other parts, due to the excessive erosion. With much wear, of course, in pumps of such construction, the efficiency falls rapidly.

5. An outstanding feature of the Rees RoTURBo Pump is that both single and multi-stage pumps are in perfect hydraulic balance, thus eliminating the expensive marine thrust bearings and balancing pistons which are always liable to wear and give trouble as soon as the clearances of same become worn through pumping gritty water. A small two-way ball thrust is usually fitted, the function of which is merely that of a centreing block to maintain alignment between the impeller and the diffusors.

6. The strong and rugged design of the impeller, diffusors and casing insures complete freedom from noise and vibration.

7. The pump is especially suitable for use with liquid of a gritty or viscous nature, owing to the low velocity through the impeller and casing, and has been largely used for pumping thick oil, sugar, liquids, etc.

8. From a mechanical point of view the pump is fully standardized and all wearing parts are easily replaceable, being made to gauge and kept in stock, thus permitting quick shipments on receipts of orders for repairs. The design of the pump is specially adapted for a wide range of duties with a given pattern by small alterations, thus reducing the number of patterns carried to a minimum and enabling us to completely standardize all parts.

From the foregoing history, and detailed description of these pumps, it will be noted that efficiency is a very strong feature. These pumps are now being built in Canada, by the Goldie McCulloch Co., Limited, of Galt, Ont., who have secured the sole rights for these pumps in the Dominion.

AUTUMN MEETING OF ELECTRICAL ENG.

Review of Work Undertaken at the Ottawa Conference—Papers Are Read

The first autumn meeting of the Toronto Section, the American Institute of Electrical Engineers, was held in the Engineers' Club, Friday, October 24. A review of the work accomplished by the National Industrial Conference held at Ottawa was presented by Mr. Frank R. Ewart, representative of the institute. The appointment of engineering delegates representing the various societies was a recognition of the engineer's status as one who, while coming into intimate contact with both the manufacturer and laborer, yet was in a position where impartial judgment and knowledge might be expected. One of the most noticeable things about the proceedings of the conference was the complete and accurate information of the labor delegates. When one of them spoke, no time was wasted in preliminary remarks, but the whole time available to the speaker was made use of in the presenting of information vital to the cause of labor. The briefs presented by those representing the manufacturing element of the community in some cases were not so well prepared, nor did they show such a familiarity with statistics and other information pertinent to labor. Mr. Ewart's further remarks had to do with the various topics of the agenda and the manner in which they were treated. In the discussion which followed, Wills McLachlan emphasized the importance of the necessity for thorough knowledge of economics on the part of both manufacturer and engineer. Both should be as familiar with the subject as was the laboring element of the community.

An interesting paper on water-turbine design was read by Mr. Adolph Eberli, hydraulic engineer, the Hydro Power Electric Commission of Ontario. Information regarding the design of this prime mover was given, and in the paper itself and in the discussion which followed, interesting facts regarding present-day developments were brought out. The Francis turbine, which is used almost universally up to high heads, is only a development, so far as its present design is concerned, of the past twenty odd years. It was formerly thought only suitable for moderate heads, but is now used everywhere, except where exceptionally high heads are encountered, as in mountainous districts. The turbines being built for the Chippewa-Queenston development are of this type.

In a recent paper presented before the American Society of Mechanical Engineers Mr. N. C. Harrison defines pulverized coal as coal that has been reduced to such fine particles that at least 95 per cent. will pass through a 100-mesh sieve having 10,000 openings to the square inch. In other words 95 per cent. must be less than one two-hundredth of an inch cube. He goes on to say that "the average person does not fully realize to what a high degree of fineness it is possible to reduce the coal to-day by pulverization. The finer coal is pulverized the more efficiently it can be burned and the more readily it will be diffused when mixed with the air for combustion and fed into the furnaces. Pulverizing certainly does not change the nature of the coal, but it does change its form to a certain extent in that the coal is changed from a solid into a fuel having liquid properties. As the coal is pulverized it is mixed with air, and when handled in the conveyor it flows like water; when fed to the furnaces it is more or less like a gas, and the furnaces must be designed to burn a gaseous mixture."

The St. Lawrence Welding Company of Montreal, have acquired a property adjoining their present plant, which they are now preparing for the installation of the equipment necessary for their tank manufacturing enterprise. Plans now under way will provide this company with adequate facilities for making any size of tank for industrial or domestic purposes. Several machine units have already been ordered and negotiations for others are in progress. The new tank shop will take care of all classes of work up to ½ inch thickness of plate. The company is continually adding to their general equipment; the machine shop has been enlarged, and by the first of the year they will be in a position to take on almost any class of repair work—welding or machine, or both. Their portable electric welding outfit is so mounted that it can be taken to any section of the country where local apparatus is not available for this purpose. The company are now accepting tank orders for delivery after the first of December.

A. W. Swan, who has been associated with the Canadian Ingersoll-Rand Company, of Sherbrooke, for the last two years, has resigned to take over the position of assistant-secretary for the Engineering Institute of Canada, in the head office at Montreal. Mr. Swan graduated from the University of Toronto, with a B.A.Sc. in 1917 and entered the production department of the Can. Ingersoll-Rand Co. Since March, 1918, he has been assistant in the publicity department, in charge of technical journal advertising.

Handy Tools for the Maintenance Man--II.

A Compilation of Various Devices and Methods Used by the Maintenance Man, Facilitating Wiring and Electrical Installations

By JAMES A. PERRY

(Copyright. All rights reserved)

EVERY wireman knows how to make a drill for forming holes in brick work, from a piece of conduit or pipe. Most of them, however, do not appear to understand how the teeth of the drill can be formed so that the drill will clear itself, that is, that it can be withdrawn from the hole without binding.

The teeth in a conduit brick drill are cut, as shown at Fig. 15B, with a three-coronered or half-round file. Although it appears inconsistent, the work can be done better and quicker with a half-round file than with a three-cornered one. Where files are not available, a hacksaw can be used for cutting the teeth, but this tool is not as good as a file, because of the liability of breaking the hacksaw blades. After the teeth have been cut, the end of the drill can be held projecting about ¼ in. over some solid object, and the ends of the teeth should be spread out, possibly 1/16 in. beyond the normal surface of the conduit with the ball end of a ball-peen hammer.

It is always a good scheme to thread the end of a conduit brick drill and run a coupling on it as shown at A, Fig. 15, to protect the thread. In spite of all precautions, these drills will sometimes bind in a hole. If one does, and its end is threaded, the protective coupling can be removed and a pipe T run on as shown in Fig. 16. Then a length of pipe of a smaller diameter is pushed through the open hole of the T. This short pipe can be used as a lever, whereby the drill can be turned in the hole and loosened, or one can pound against the short pipe and thereby force the drill from the hole.

For drilling in concrete or masonry harder than brick, a drill of the type suggested in Fig. 17 is best fitted. This is forged from hexagonal tool-steel stock. The cutting edge of the drill is formed somewhat like that on a cold chisel, except that it should be rounding, and that clearance should be provided as suggested. In using this drill, its head is pounded with a heavy hammer and the drill is turned a portion of a revolution between each blow. This will tend to make a cylindrical hole and prevent the drill from wedging in it.

Wherever many holes are to be drilled in concrete, either an air or electric drill should be purchased. The justification for such an investment can be readily shown if one figures the cost of labor for drilling with a machine, and then the cost for hand drilling.

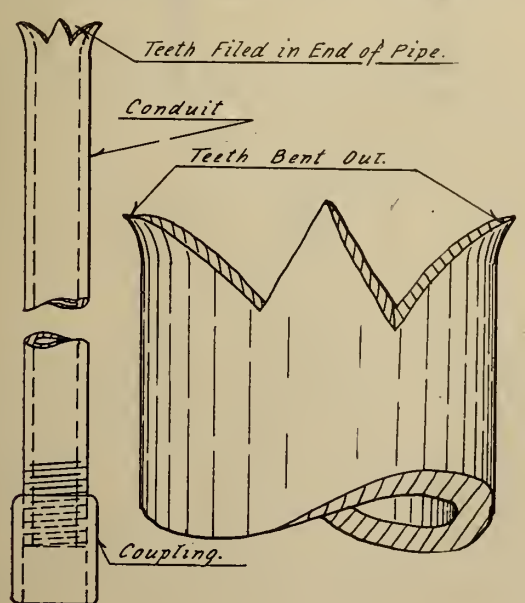

FIG. 15—DETAILS OF A BRICK DRILL

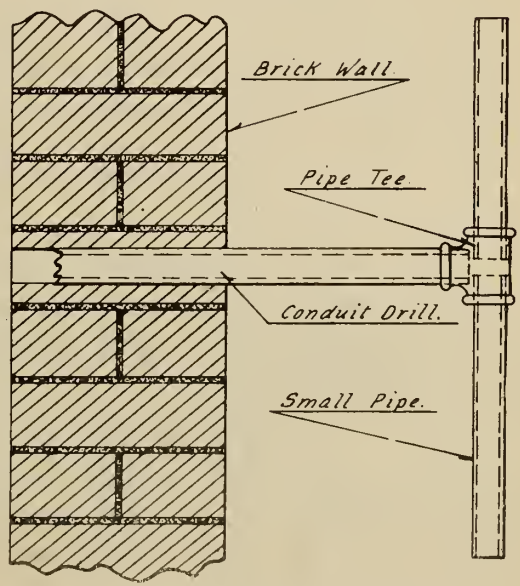

FIG. 16—REMOVING BRICK DRILL FROM WALL.

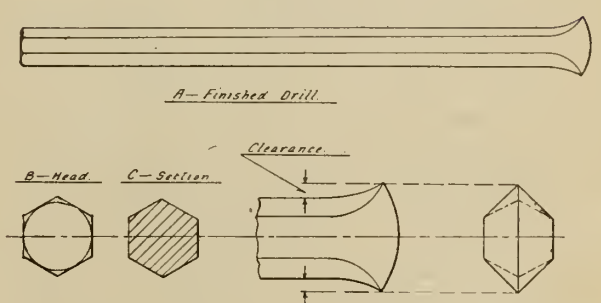

FIG. 17—DRILL FOR CONCRETE OR STONE.

It is often necessary to bore holes in locations where the ordinary brace cannot be used. Examples are the holes that must be bored in pockets in finished building wiring through joists or floor plates. If the wireman will carry in his kit a door knob or valve wheel (Fig. 18) he can turn an ordinary bit with one of these handles, and so cut holes in these restricted places. For a permanent tool, probably a door knob, Fig. 18 H, is best. Its rounding smooth surface fits the palm of the hand, and the bit can be firmly held in it by the screw that is always provided in the metal part of the knob. A V-shaped groove should be filed in the shank of the bit, into which the end of this tightening screw can engage. For a satisfactory operation with one of these handles the bit should be kept very sharp.

An operation that is usually very tedious is the fishing of electric fixtures. This is particularly true when wires must be drawn through small-diameter arms that are formed into right-angle curves. A splendid home-made device for getting a pulling-in wire through these irregular arms can be made as shown in Fig. 19. A piece of fishing line is tied to the end of a length of bead chain, such as that used for pull-chain sockets. It will be found that when the chain is inserted into the tube that it will

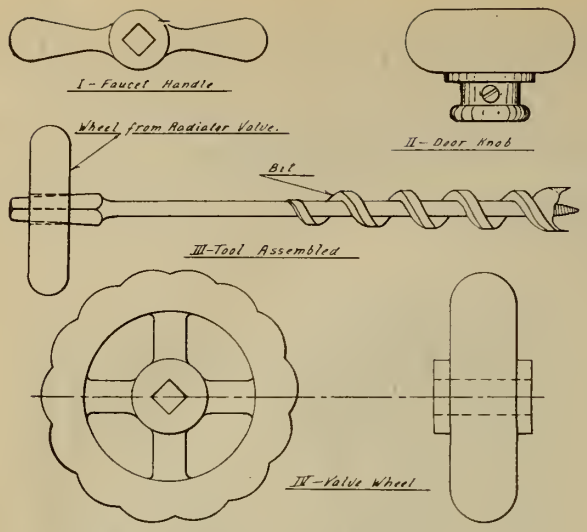

FIG. 18—HOME-MADE BORING TOOL.

follow all of the curves very readily, and draw in the fishing line. The fixture wires can be easily attached to this line and then pulled into place. The bead chain will even pass around a right-angle curve.

Another method that can be used for fishing fixture arms if bead chain is not available, is as follows:—The end of a length of strong thread is rolled with the fingers into a little ball. This ball is placed, with the end of the thread extending, into the fixture arm. Then by blowing into the arm the ball will be forced through, and the thread can be fed in after it. With the thread a stronger piece of twine or a small wire to serve as a pulling-in line can be drawn in.

When a wireman has a great many fixtures to install, the quickest way of handling the job is to scrape and twist connections for possibly fifty of them, and then solder and tape them later. This procedure saves time, and hence, money. Furthermore, if the ladle method later described, is used, splotches of solder on the floors can be avoided, and there will be no blackening of the ceilings that occurs when joints are soldered with a blow torch.

The soldering of the fixture connections in a job like that above referred to can be most readily affected by using a small ladle such as that indicated in Figs. 20 and 21. Either of these ladles can be heated by the ordinary blow torch. In soldering, it is only necessary to dip the twisted and fluxed ends of the fixture connections into the little pot of molten solder, and then strike the connection a tap or two with the hand to knock off the surplus solder.

The ladle of Fig. 20 is made by screwing a part of a steel armored cable bushing into a ½-in. gas cap. This

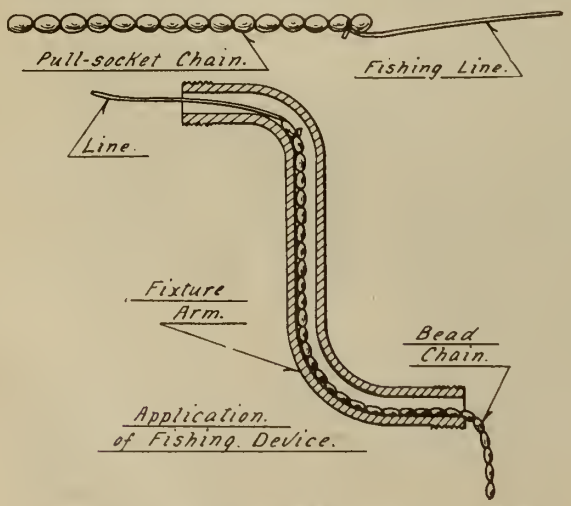

FIG. 19—BEAD CHAIN FOR FISHING FIXTURES.

provides a holder in which the wire of the handle can engage.

Another method of making a soldering ladle of a little larger capacity is shown in Fig. 21. In this, four holes are bored in a ½-in. or ¾-in. pipe cap, and the wire for the handle is threaded through them as shown. The cap cannot turn in the wires, hence, the threading provides a very substantial attachment. A wood handle (Fig. 21)

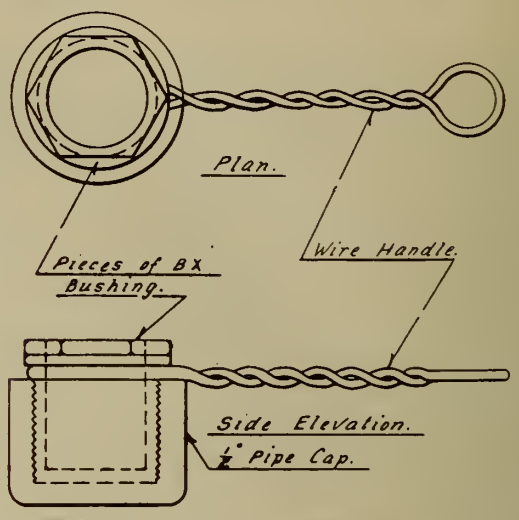

FIG. 20—LADLE FOR SOLDERING LEADS.

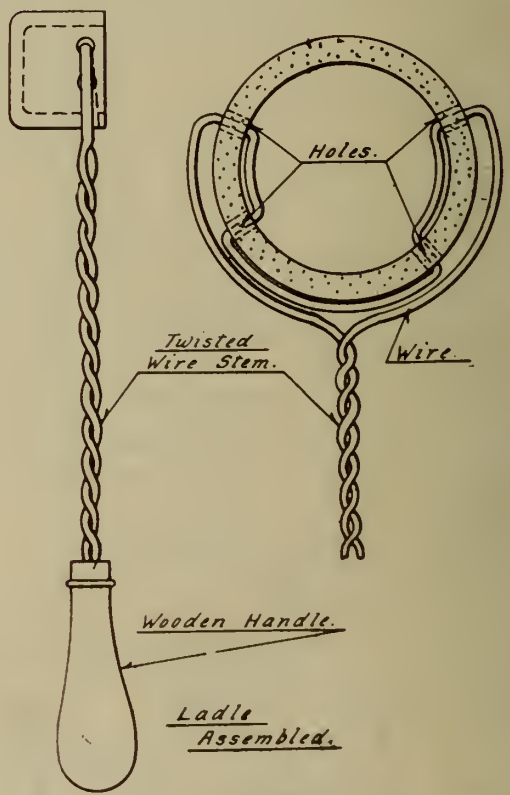

FIG. 21—LONG-HANDLED LADLE.

will be found very convenient, because if the handle is made of wire only, it is apt to become uncomfortably hot.

How to best carry his soldering paste is usually somewhat of a problem to the average wireman. It is supplied by the manufacturers in cylindrical tin or pasteboard containers, which are of rather inconvenient size to carry to the points where the soldering is being done. One scheme that has worked out very well in practice, is to transfer to a grease cup some of the paste and to use the grease cup in feeding it to the joint to be soldered. Fig. 22 shows grease cups of two types used for this

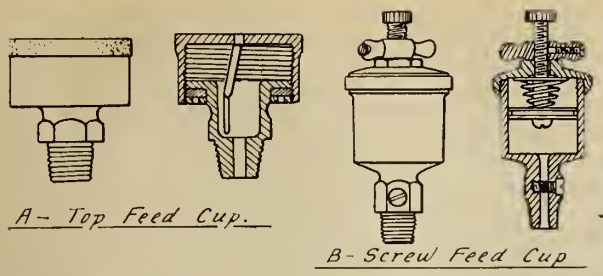

FIG. 22.—GREASE CUPS FOR CARRYING SOLDERING PASTE.

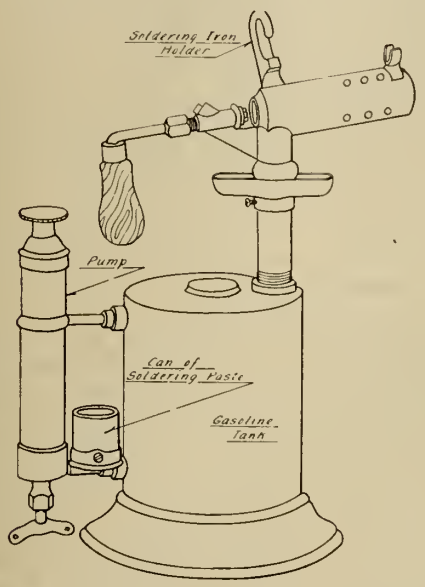

FIG. 23—PASTE CAN ON BLOW TORCH.

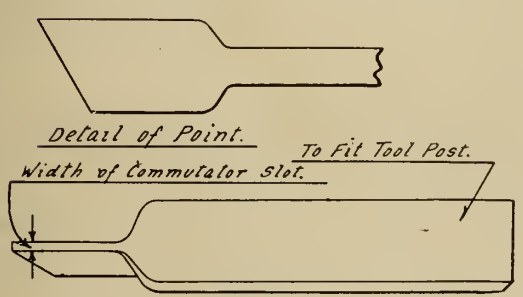

FIG. 24—TOOL FOR SLOTTING COMMUTATORS.

purpose. In that of A, which is the cheaper, the paste is fed through the orifice by turning the top. A steel retarding spring, which will fit into a groove at each revolution, prevents the cap from unscrewing easily. The grease cup at B is the most convenient because the paste can be fed either by a direct push on the feed plunger or by turning the feed handle. Furthermore, the valve screw provides a means whereby the cap can be entirely closed before it is placed in the wireman's kit for the night, or for transportation.

Another method of carrying paste that has been used by some wiremen is that shown in Fig. 23. In this, a small can to contain the paste can be directly attached to the blow torch by using a piece of a shade holder. This makes a very convenient arrangement for certain kinds of work. By loosening the set screw in the holder the can can be easily removed for re-filling.

Sometimes the electrician finds it necessary to re-slot commutators that were formerly slotted, but that have worn down, or to cut mica from those that were not, but which should have been, slotted by their manufacturers. For a makeshift arrangement, the mica can be scraped out with the edge of a hacksaw blade, but a much better and more accurate tool is that shown in Fig. 24. It is forged from a piece of tool steel, and in use is held in the tool post of a lathe. The armature that carries the commutator to be slotted is maintained between the centres of the lathe. Then the slide rest with the tool described and its tool post is worked back and forth. Each time it goes forward, the tool should be set to cut some of the mica from between two commutator segments. The action is, in a general way, similar to that of a planer or shaper. After one slot has been cut to a sufficient depth, the armature is rotated and the next one cut, and so on, until the entire armature has been re-slotted.

Screw-drivers especially designed for starting screws, that is, to hold the screw in the end of the driver for insertion in inaccessible places, are regularly made by the manufacturers. Their prices are very reasonable, hence, if one requires a screw starter, he will probably find it most economical to purchase the commercial article. However, if such for some reason or other is not available, he can make one for himself as shown in Fig. 25. The end of an old screw-driver is cut off square, as shown at A. A slot is sawed in the end. Into this slot, two pieces of clock spring, possibly 1 in. long x ¼ in. wide, are soldered. The pieces to be soldered should all be filed bright, and tinned with sal-ammoniac as a flux before they are inserted in the slot. After they have been thus prepared and inserted, additional solder should be sweated on. In using the tool, the two clock-spring levers are pressed together and inserted in the slot of the screw. When the pressure on them is released, they will grip the screw and hold it while it is being started.

Every man that does much knob-and-tube work must have thought at some time or another of the time that is required to string leather heads, that is, to insert the nails in the leather washers that are used with porcelain

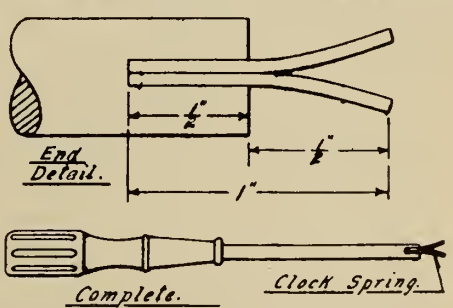

FIG. 25—SCREW-HOLDER FOR SCREW DRIVER

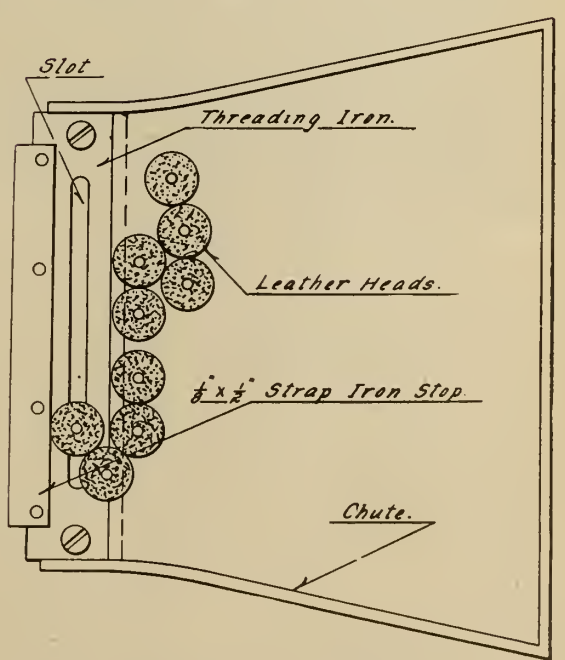

FIG. 26—PLAN VIEW OF STRINGING DEVICE.

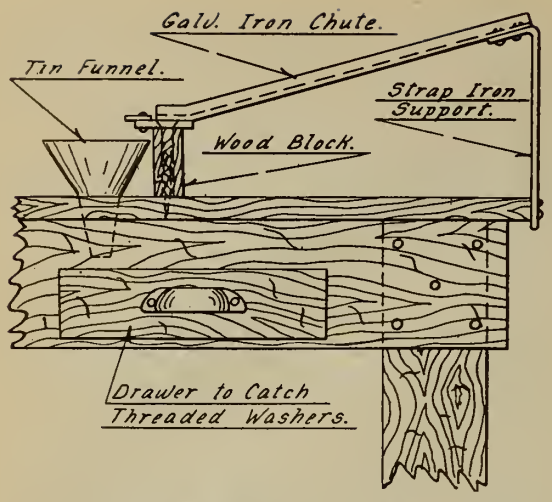

FIG. 27—STRINGING DEVICE MOUNTED ON BENCH.

knobs and cleats to prevent the breaking of the porcelain. Figs. 26 and 27 show a simple device, whereby this threading can be accomplished quickly and with minimum labor. In a large shop the threading device should be installed in the stock room. Then the stock-boy can use his spare time in putting nails in the leather heads. When the nails are drawn out of stock for a job, the leather heads will be in place on them, already for insertion in the knobs. The arrangement consists (Figs. 26 and 27) of a galvanized-iron inclined chute into which a supply of leather heads is dumped. The heads slide down against a stop of ⅛ in. x ½ in. strap iron. When they are in this position, the holes in the heads lie directly over a slot in the threading iron, and a nail is driven into each leather head and into the slot. Then the nail and the leather head are taken up and dropped through the funnel into the drawer prepared for their eception. The constant pounding causes the heads to continuously slide down the chute, hence, as soon as a nail is driven into one head and it is removed, another head slides down to take its place.

The "Natural Law" of Steam Boiler Performance

IF a steam boiler is recognized as an apparatus for converting heat energy in fuel into heat energy in steam with atmospheric air as the medium of conversion, then it can naturally be expected that the process of conversion will take place in accordance with the laws governing the medium in the same way as it is governed in other analogous processes. As a matter of fact, the expectation is entirely fulfilled. In order that the readers of the *Engineer* may have no doubts on the matter, and also that they may be in a position to verify the fact for themselves, the writer gives the two cases of internal combustion engines and steam boilers in such a form that a glance will almost be sufficient to convince them.

If T E = thermal efficiency of boiler expressed as a fraction,

R = rate of combustion in B.Th.U. per cubic foot of air used,

and Q = quantity of air in cubic feet per pound of water evaporated from and at 212 deg. Fah.

$$\text{then } Q = \frac{966}{T\,E \times R}$$

That is to say, quite independent of their size or type, quite independent of the soot or scale on their surfaces, and quite independent of the class or calorific value to the fuel they use, all steam boilers that realize the same standard of thermal efficiency use the same quantity of air per pound of water evaporated from and at 212 deg. Fah. With regard to evaporation per square foot of heating surface, different types of boilers present their heating surfaces in different positions towards the heated air passing over the surfaces, and as a consequence each type of boiler has a characteristic factor of its own. Also the ratio of heating surface to flue area is different in different size boilers of similar type, as well as in boilers of different type. Taking these factors into account, the reader will be in a position to predict the performance of any boiler.

Finally, all the fuel fired is not burnt, and a factor that expresses the proportion actually burnt in proportion to ashes and to cinders carried away by forced draught must be used, or the rate of combustion would not be accurately or even approximately known.

JAMES DUNLOP, in the *Engineer*.

Internal Combustion Engines

P = any higher pressure in pounds per square inch absolute.
p = any lower pressure in pounds per square inch absolute.
S = stroke volume of cylinder expressed as unity.
V = clearance volume of cylinder expressed as a fraction.
S* = stroke volume expressed as a fraction for scavenging pumps and air compressors.

$$\sqrt[4]{\frac{P}{p}} = \sqrt[3]{\frac{V+S}{V}}$$

$$\frac{P}{p} = \sqrt[4]{\left\{\frac{V+S}{V}\right\}^3} \qquad \frac{V+S}{V} = \sqrt[3]{\left\{\frac{P}{p}\right\}^4}$$

$$P = p\sqrt[4]{\left\{\frac{V+S}{V}\right\}^3} \qquad S^* = \frac{\sqrt[3]{\left\{\frac{P}{p}\right\}^4} - 1}{\sqrt[3]{\left\{\frac{P}{p}\right\}^4} - 1}$$

$$p = \frac{P}{\sqrt[4]{\left\{\frac{V+S}{V}\right\}^3}} \qquad V = \frac{S}{\sqrt[3]{\left\{\frac{P}{p}\right\}^4} - 1}$$

Steam Boilers

F = any higher rate of firing in pounds per square foot of grate area.
f = any lower rate of firing in pounds per square foot of grate area.
E = any higher rate of evaporation in pounds per square foot of heating surface.
e = any lower rate of evaporation in pounds per square foot of heating surface.

$$\sqrt[4]{\frac{F}{f}} = \sqrt[3]{\frac{E}{e}}$$

$$\frac{F}{f} = \sqrt[3]{\left\{\frac{E}{e}\right\}^4} \qquad \frac{E}{e} = \sqrt[4]{\left\{\frac{F}{f}\right\}^3}$$

$$F = f\sqrt[3]{\left\{\frac{E}{e}\right\}^4} \qquad E = e\sqrt[4]{\left\{\frac{F}{f}\right\}^3}$$

$$f = \frac{F}{\sqrt[3]{\left\{\frac{E}{e}\right\}^4}} \qquad e = \frac{E}{\sqrt[4]{\left\{\frac{F}{f}\right\}^3}}$$

SELECTING AND TESTING SHOP SUPPLIES

By F. E. Merriman

So many and rapid are the changes taking place even in quite staple goods that an article best suited to a specific purpose to-day may not fairly lay claim to that distinction a few months later. New styles, kinds and varieties of goods are constantly developed and placed on the market and so demand the continual attention of the manufacturer who would exercise maximum economy in the purchase of his supplies. Furthermore, "quality" is becoming more and more the slogan of the manufacturer and this makes many articles available for use though, heretofore, found unsuitable. This, of course, raises the question of how best to make the selection and how to keep apace with changes, for some knowledge of all improvements is essential to those purchasing.

Manufacturers and buyers are taking note of improvements and developments in their supplies and checking them against their requirements in various ways. The large manufacturer has his testing laboratories and corps to keep him informed of the value of these things, others ignore them and stick to past practice; but many cannot afford the first and are unwilling to follow the other policy. To the manufacturer unable to have a laboratory there are other less expensive, and often equally as efficient, methods open. It is the purpose of this article to discuss a few practical instances of simple, inexpensive, but reliable comparisons of articles and goods of common use in manufacturing plants.

Belting is a material in common use in factories; but concerning the merits of the various kinds there is much prejudice, diversity of opinion and experience. There is, first of all, leather of various makes, tannages and methods of manufacture. Again there are belts which are of woven material and impregnated with various substances, also rubber belts, all having their uses and successful installations. Regarding their relative merits for a particular plant no general conclusion can be drawn, for every plant has a variety of drives and operating conditions to which certain kinds of belting are much better suited than others. The fallacy of expecting to use one kind of belting throughout a factory needs much emphasis, for it is a very common error. Many can be found who will say and believe that leather, or some other particular kind of belting, is the best for all purposes. It is well known high speed steel is better than carbon tool steel for certain places and conditions, but no one would think of recommending it as the best for every purpose. The same is true of beltings, they will have their application. This short discussion has shown that to properly select belting we must first of all understand the general characteristics of the various kinds available. This, of course, calls originally for some kind of a trial and there is none better than a practical application to the various types of drives about the factory. To determine what these types are, requires some knowledge of the factory and some analysis. To illustrate the idea, there are drives where rubbing occurs, due to belt shifters, drives where the belts run over small pulleys, belts with idlers and tighteners, high or low speed belts, vertical belts, horizontal belts, long and short centre distances between driver and driver pulleys, high and low powered belts, wet surroundings, greasy drives, etc., all common to nearly every factory. All these conditions call for certain common characteristics in belts and qualities necessary for a certain drive may not be at all essential to others. A little study shows what the most important characteristics are. For example, a belt where a shifter is used must successfully resist rubbing on the edges, small pulleys are more destructive than large, because they bend the belt to a greater extent. Excessive moisture or oil, when present, increase the tractive difficulty as do short drives. The horizontal drive is easier than the vertical drive. A practical belt test under such conditions discloses its characteristics in these particulars. It shows that leather resists rubbing on the edges better than belts from woven materials. Also under certain greasy conditions leather will not always do as well as certain other materials.

To obtain a reasonable idea of the value of various kinds of belting need be neither expensive nor yet long drawn out. Drives selected for test should be of sufficient difficulty to disclose the merits of the tested material in a short time. Such a test, when the material fails, often discloses characteristics valuable and sometimes superior for other applications. A brief trial or two of this kind usually furnishes the information necessary to determine where further tests can advantageously be made. Drives where trouble is found often furnish suitable places for a trial. In this connection a warning may well be sounded against too severe a test, for really good material has sometimes been condemned by senseless and unreasonable tests. Common sense is as necessary here as elsewhere.

An illustration of the knowledge gained from a test of this character will be of interest. The drive was from a main line to a countershaft. Considerable power was transmitted and, due to the presence of a clutch, considerable oil was present. It was considered a difficult drive. Oak leather was the initial belt and afterward two woven belts were used on two similar drives with very close to the same conditions. One of the trial belts was of woven material folded to make several plies and finally stitched together and impregnated with a waterproofing substance. The other was woven to the desired thickness in one ply. The results were as follows: The leather belt became saturated with oil and then lost its tractive capacity; the folded and stitched belt ran successfully until the outer ply wore out, including the stitching, the plies then separated and the destruction of the belt soon followed. The third belt was still running in good condition long after the others were useless. It was found that the second belt carried the drive as long as three leather belts and not as long as the third trial belt. The leather belt, however, had a reclaim value not possessed by the woven belts.

Cost of 3 leather belts	$24.62
Reclaim value	14.77
Belting cost	9.85
Cost of folded belt	4.78
Saving over leather belt	5.07
Cost of single ply belt	3.51
Saving over leather belt	6.34

The lesser risk of shut down in the case either of the two belts tested was of considerable value and a still larger balance in their favor could readily be shown.

The success of the institched belt in this trial suggested its use for a spindle drive on the radial arm of a large drill press where, due to a poorly arranged oiling system, much oil was present. This made it a difficult drive for leather belting. The trial belt here was a success, though the life was not great, due to the destructive effect of the small pulleys used.

Another installation, a wet grinder, proved a leather belt of special tannage, superior to anything else, for it had long life and excellent driving power, notwithstanding the large amount of water present. The other belts were less successful under these circumstances.

These tests all required some time and attention, but most of this was furnished by the millwright foreman, who was easily interested in making the tests. In fact it was the interest on the part of this foreman which was instrumental in carrying the test to a successful conclusion in each case. The point of greatest interest is, however, the fact that the tests were made with no interruption of regular factory operation and at practically no expense. The results were worth many dollars to the firm.

One of the much-mooted questions in many factories is the question of a proper cutting lubricant. Many hold there is nothing equal to a good grade lard oil. Others, however, find an advantage in the use of other fluids. Due to the many variable conditions present such as the operator's opinion, the quality of the cutting tools, the grade and condition of the material worked, etc., definite comparisons of performance are not readily set up. However, an analysis of these conditions will point out what may be called a typical job on which the cutting fluid may be given a trial. The result of such a trial will demonstrate in many instances the value of the goods not only for the job, but also for the usual run of work.

The Isolated Plant

PRESENT tendencies in power plant engineering point to the elimination of the small plant. The power salesman plays up the resulting saving in labor, cleanliness and general economy effected. All of this may be true of the summer months but in a manufacturing plant of any size the heating question is one of considerable magnitude and steam is required for a not inconsiderable part of every year. This is apart from the fact that many industries require heat the year round for process work.

Where a boiler plant is installed for any purpose whatever, the most logical method would seem to require the installation of engine or turbine and the generation of power to whatever extent possible. Little extra fuel would be necessary and the power made would be so much velvet, consideration being given to operating and capital charges. Furthermore, the isolated plant using exhaust steam for heating or process work is a direct aid to conservation.

The difficulty with the isolated plant operating under these conditions and a talking point, used by the power salesman is the costliness of summer power when heating is no longer required and the suggestion has been advanced to the effect that the small plant be hooked up with the central station. This would result in the central station supplying the summer load, while the isolated plant carried the winter one and fed power in a reverse direction if too much for private needs were generated.

This sounds quite attractive, but the actual working out of the problem is not so easy with direct current or alternating current generators of the usual type. Experienced operators would seem to be necessary, and metering and billing would be complicated.

It has been suggested of late that the many small water-powers not now developed be utilized and tied up with the transmission lines of large power companies. The induction generator has been advanced as suitable equipment and the small plant made automatic in operation. This same type of generator might find use in the isolated plant tied in with the larger power company. Electrical operating problems would be reduced to the vanishing point and great flexibility would result.

The relieving of the central station load during the winter months would be of advantage to them in the smoothing out of the yearly load curve.

Harnessing the Wind

COINCIDENTAL with the growing interest manifest in fuel conservation in various forms, an increasing interest is evident in the utilization of, at present, waste forms of energy. The power of the tides is a fertile field for inventors, and many and varied have been the schemes proposed for its harnessing. Wave motors, too, have received their share of attention, but, like the extracting of gold from sea water, the capital cost of development greatly outweighs any resultant revenue.

The harnessing of the wind, while practiced on a small scale in the familiar farm windmill, has never been seriously attempted, and there are many who anticipate great things when this is accomplished. The other side of the question also has its adherents, and these hold to the opinion that little or nothing will come of attempts to utilize this power.

The truth of the matter probably lies between the two extremes, and the windmill in moderate sizes will find a useful service to perform where the power required is not of large volume. Large size is not economical whether from the standpoint of efficiency or from economy in cost and operation, two twelve-foot mills giving better results than one sixteen-foot mill.

While the windmill has one considerable advantage in that the cost of the energy used is nothing, interest and depreciation have to be taken into account, and the cost of the power rendered available is thus appreciable. With due allowance for this fact and considering the variable nature of the power available due to fluctuating winds, the windmill should find a definite sphere of utility for irrigation and agricultural purposes and other fields of like nature where the power required is small and requirements can be met by units of small horsepower.

The development of the induction type generator as an auxiliary supply of power feeding a general transmission system may here also solve some of the problems connected with the use of wind power.

Are You a Figure Fiend?

AT an early stage in our lives, most of us, possessed of any imagination whatever, wondered just how much we saved by cutting across lots instead of going around. A little later on another problem intrigued us; we wondered as to just what the relation between the diameter and circumference of a circle was. Fortunately, we had teachers, more or less accomplished, to enlighten us, but in the early stages of the development of mathematics and general science those of a philosophic mind were not so happily situated and perforce, they had to go it blind.

All problems having to do with the mensuration of the circle have to do with the ratio of the circumference to the diameter. To those not conversant with mathematics, it would appear that this should be comparatively simple and so it is of no absolute value required. The ratio commonly denoted as π is in its nature an incommensurable number, that is no fraction can be found which will give its exact value. The commonly accepted approximation of 22/7 is not strictly accurate, for when it is changed into a decimal fraction its value will be 3.142857°, whereas the true value to the same number of decimal places is 3.141592. A closer approximation than the fraction 22/7 is given by another fraction 355/113.

Perhaps the best proof of the fact that no vulgar fraction can be found which exactly represents the value of π is seen in a characteristic of all vulgar fractions. When reduced to decimals it will be found that after a certain number of divisions they repeat themselves thus: 22/7= 3.142857142857, etc. On the other hand, the number π never repeats, but runs on and on as far as one cares to figure it.

The earliest idea of the number which represented the ratio between the diameter and circumference was probably the number 3. It was so at least among the Jews (1 Kings vii:23, 26), the Babylonians, the Chinese and probably also the Greeks. Archimedes made a notable advance over former knowledge of this subject, and by geometrical means which he originated determined the fact that the true ratio lay between 3 1/7 and 310/71. His method consisted essentially of calculating the length of the sides of regular polygons inscribed in and escribed around the circle.

With the renaissance in Europe more powerful means became available and the use of formulae, in themselves an algebraic shorthand, greatly simplified the labor involved in computation. One Rudolph Van Ceulen (a.d. 1610), busied himself with the problem for the greater portion of his life and the results of his labors were not interred with him but inscribed on his tomb. He gave the result correct to 20 decimal places and as a curiosity it may be given here:

π=3.141,592,653,589,793,238,462,643,383,279,502,88.

Since his time has arisen a class of workers known as π-hunters, π-computers, or circle squarers. Their labors, fruitless though they may be, are interesting from the length to which they have carried the number. A decimal number with several hundred places is common in their results and one figure of 707 places has been reached. When compared with the modest figure given above, this number seems enormous.

Various methods have been used by these investigators for the solving of their problem and much effort has been wasted by some of them in trying to reach the end of their never-ending labors. It has been definitely proved that no such end is possible, and we must be content with approximations, of whatever degree of exactness desired.

Are You Wasting Your Time?

NOW that the winter months are almost here, what are you doing in the long winter evenings? You say you get enough of the grind all day without continuing it at night. Quite right. But did you ever stop to think that the way to get away from the grind was to grind harder?

The manner in which manufacturing is carried on now, the speed with which operations must be performed, the way in which material must be routed, all mean that the man who is going to master the situation must be a student. What was considered a job for a standard machine yesterday is moved to a special-purpose tool to-day.

What do you read? The papers? Very well, read them. Keep informed, but make certain that your information is going to be worth something to you. You read three columns of stuff about the gruesome details of a murder or a suicide or a divorce case. What better off are you? Absolutely none.

Get a direct drive in your reading. Make it a point to be well informed about some subject. People find it a pleasure to talk to you. There are successful men on the road who do this thing continuously. They enter into a conversation and turn it to a subject on which they have gathered a lot of information. They are able to talk intelligently and they get a good hearing.

You can do the same thing in your own line, no matter what it is.

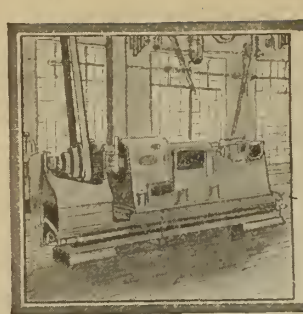
You can largely make yourself what you want to be.

Water Powers of British Columbia

THE Commission of Conservation, Ottawa, have issued to the press advance copies of an unusually complete report on the water powers of British Columbia. The report of some 650 pages is a compendium of data relating to the water power resources of the province and as such, is of much value from an engineering and reference standpoint. The opening chapters comprise a statement of the guiding principles which should govern in the conservation and utilization of inland waters, and a description of certain important features which should characterize reliable water power data. There follows a comprehensive, historical survey of water legislation in the province, together with discussions of subjects cognate thereto.

In the portion of the report which relates more particularly to physical data, will be found tabular lists of the estimated possibilities of water power sites throughout the province, which lists are based chiefly upon results obtained chiefly from the special field investigations conducted by the Commission of Conservation — Digests of stream flow, meteorological and other hydrometric records.

The Commission commenced its own reconnaissance field work in the Eastern provinces, in connection with the water power resources of the country, and in 1911 published "Water Powers of Canada," which presented in summary form the information then available for the provinces of Prince Edward Island, Nova Scotia, New Brunswick, Quebec and Ontario. In 1916 the report on the water powers of Manitoba, Saskatchewan and Alberta was issued. The present volume on "Water Powers of British Columbia" completes the series of reports on this subject. Owing to the recent war the publication of this concluding volume of the series has been delayed.



NEW POWER PLANT EQUIPMENT

"VOLYUM" CENTRIFUGAL PUMP

The Volyum Pump Co., 419 West Liberty St., Cincinnati, Ohio, have brought out a new vertical centrifugal pump, known by the trade name of "Volyum" and intended especially for supplying the coolant for machine or cutting tools. Fig. 1 shows an outside view of the device, while Fig. 2 is a sectional view showing the construction. The impeller is of the open type, mounted on the lower end of the vertical shaft and extending the full depth of the semi-spherical body, there being no contact between the impeller and the body casting. The bearings for the impeller shaft are both above the water line; one of these bearings is formed by the stuffing-box gland that is located just above the impeller, while the second one is in the cap. The drive from the pulley is through two spiral gears, placed at right angles and having a 3 to 1 ratio. The large gear is mounted on the driving shaft and runs in oil in the chamber formed by the cover, this oil serving to lubricate both the shafts and the thrust bearings, as well as the gear teeth themselves. A 3-in. flanged pulley is standard equipment, although a gear or sprocket wheel can be substituted if desired. The pump can be mounted on either the side or end of a machine, as desired, various angles of drive being obtained by swiveling the cover in relation to the body and by reversing the position of the pulley. In order to eliminate the loss of the liquid necessary for priming, the suction pipe is located above the delivery box and the body thus retains a full supply of liquid. The pump is at present made for ¾-in. pipe connections, and has a capacity of from 5 to 22 gal. per minute, depending upon the speed.

In the United States the great reserves of shales that contain oil are still untouched. These shales are found in many parts of the country, and tremendous reserves are known to exist in Colorado, Utah, and Wyoming. Some of the American shales are much richer in oil than are the Scotch shades, and are conservatively estimated to contain many times the amount of oil that has been or will be produced from all the porous formations in the country. The recovery of oil from shale has never been followed in America because of the lack of necessity, for the oil reserves are great, and it would not be commercially economical to invest money in retorts for distilling oil from shale that would have to compete with the crude oil obtained by other methods. But this condition will not last for ever. In fact, it is thought that it will be only a very short time before the oil shale industry will be of considerable magnitude.

The world's two deepest wells, penetrating to depths of 7,579 feet and 7,386 feet respectively, are, according to the "Engineering News Record," the Lake, near Fairmont, W. Va., and the Goff, near Clarksburg. These wells were sunk by the Hope Natural Gas Company, of Pittsburgh, in an endeavor to reach the rich oil-bearing Clinton sand of Ohio, which it was hoped to encounter at depths between 7,000 feet and 8,000 feet. Another well, the Geary, was sunk near McDonald, Penn., to a depth of 7.248 feet by the People's Natural Gas Company. It is the fourth deepest, a well at Czuchow, Germany, according to the United States Geological Survey, exceeding the depth of the Geary by 100 feet.

Ask Government Control of Ferries —A delegation from Windsor has gone to Ottawa to try and secure Government control for the Detroit-Windsor ferries. Parliament will be asked to amend the customs act under which ferry companies operate in Canadian waters The company can at present charge any fare it likes, as it is operating without license from the Dominion authorities.

The Operators' Point of View

MAXIMUM PITCH OF RIVETED JOINTS

By John S. Watts

The following rule for finding the maximum pitch of rivets to be allowed in the riveted joints of a boiler is found in the regulations of all of the following authorities: British Board of Trade; Dominion of Canada—for marine boilers. All the Provincial Governments in Canada have enacted regulations for the construction and inspection of boilers.

The formula is:

$$Pm = (C \times T) + 1\frac{5}{8} \text{ in.}$$

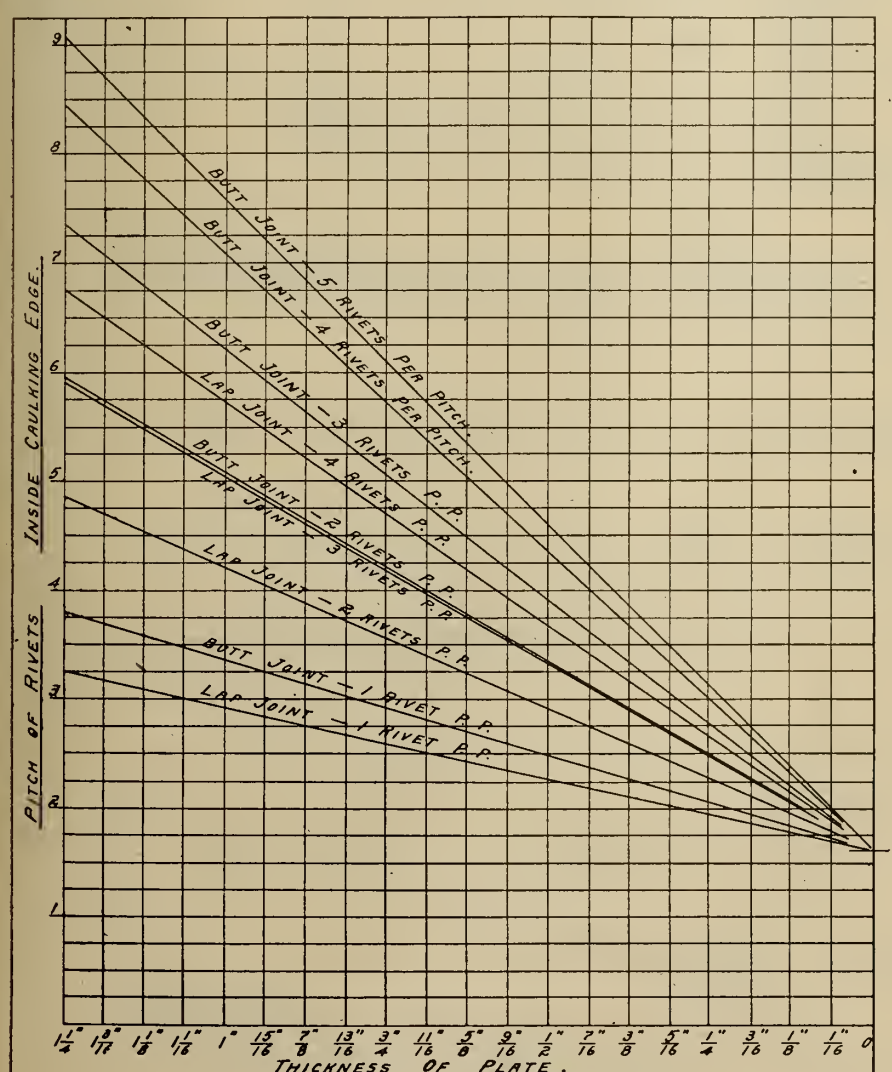
When Pm = Maximum pitch of rivets in inches (not to exceed 10 inches) immediately inside the caulking edge or edges.

C = Constant applicable from the following table.

T = Thickness of plate in inches.

Number of rivets in one pitch	Constant for lap joints	Constant for double butt strap joints
1	1.31	1.75
2	2.62	3.50
3	3.47	4.63
4	4.14	5.52
5	...	6.00

To save the time necessary to work out this formula, the accompanying chart has been drawn, from which, by measuring on the vertical line corresponding to the thickness of the plate in question, the distance from the base line to the intersection of the aforesaid vertical line, with the diagonal line marked to correspond with the type of joint under consideration, will give the length of the maximum pitch allowed.



PITCH OF RIVETS
INSIDE CAULKING EDGE.
BUTT JOINT — 5 RIVETS PER PITCH.
BUTT JOINT — 4 RIVETS PER PITCH.
BUTT JOINT — 3 RIVETS P. P.
LAP JOINT — 4 RIVETS P. P.
BUTT JOINT — 2 RIVETS P. P.
LAP JOINT — 3 RIVETS P. P.
LAP JOINT — 2 RIVETS P. P.
BUTT JOINT — 1 RIVET P. P.
LAP JOINT — 1 RIVET P. P.
THICKNESS OF PLATE.

CHART FOR MAXIMUM PITCH OF RIVETED JOINTS.

For example, take a ½ inch plate with a butt joint having three rivets per pitch, the maximum pitch according to the chart is slightly over 3 15-16 in. According to the formulae it is $(4.63 \times \frac{1}{2}) + 1\frac{5}{8}$ in. = 3.94 in.

For the benefit of those draftsmen who have not had the advantage of shop experience, it may be added that the reason for this rule is that it is difficult to caulk a boiler so as to be permanently steam tight with wider pitches than allowed by the rule, as the plate, when being caulked, tends to spring up between the rivets when they are too widely spaced.

Another point in connection with this rule as regards the butt strapped joints, is that it assumes that the butt straps are ⅝ of the thickness of the plate. As the thickness of the butt strap is what decides the ability of the joint to stand caulking, it would appear logical that if a thicker butt strap is used, the maximum pitch of the rivets could be increased to that allowed for a plate whose thickness is 8-5 of the thickness of the butt strap. The writer does not recommend doing this as a standard practice, and there is nothing in the rules to cover this point, either for or against, but some inspectors allow it to be done, and in special cases the point may be worth remembering.

A REPLY TO JUSTICE

The Editor:—

I have been greatly amused reading the letter of one who calls himself Justice, Grade Certificates. Now, sir, to my way of thinking, this upstart—this would-be engineer—would be more in keeping with his name if he had signed it Bolshevik. He finds fault with the act for allowing an engineer, who has had charge of a plant of 150 h.p., to remain in charge of his plant. According to this man the older engineers—men who have come up from the ranks and distinguished themselves, showing to their employers by their ability that they were efficient and worthy of a position of trust—this man who signs his name Justice would throw these men into the discard, and by the tone of his letter he would like to step into one of the jobs left vacant.

Now, sir, as an engineer, who, through the working of this act, may be placed after the first of January in charge of a plant of unlimited capacity—I would like to register a kick. The agitation in this province for the grading of engineers' certificates has been of some

years' duration. The writer of this letter has been down to the Legislature on several occasions, as one of a body of engineers asking the Government to give us graded certificates. Sufficient opposition to offset our demands came through an organization in one of our large cities, and the consequence was that we have been unable to secure any legislation until quite recently. Many of the engineers who have been influential in the securing of this act are placed in an embarrassing position by the wording of the act.

I refer to those engineers who will be left in charge of plants of unlimited capacities. These men, who are to-day handling efficiently large plants and who know the ins and outs of engineering from A to Z, may not be able to sit down at a desk and figure out the intricate problems in higher mathematics and so forth, as required to secure a first-class certificate; yet, they have the confidence of their employers and are able to direct a body of men in the economical operation of large steam plants. I claim that an injustice will be perpetrated on these engineers if they are not granted a certificate in keeping with the position they hold. When a man reaches the age of 50 or thereabouts, his mental abilities are not as easily exercised as they would be at 20 or 30, and a man who has the care and responsibility of a large plant on his mind cannot find time to devote his attention to learning the highly technical end without dropping something else. These men should be taken care of in our new legislation and granted first-class certificates. Any old loophole was good enough to let a man qualify when the Government first granted certificates. Now our Bolshevik friend would give us a year to prepare for an examination, and if we fail why let him have the job. He does not tell us why, with all of his qualifications, that he is not in charge of a large plant. Surely, with all the ability that he is making claim to, he could have persuaded some of our large plant owners to have given him a position. He forgets that the chiefs in charge of large plants have proven their ability; they have also studied hard and improved their knowledge, and have demonstrated to those in authority that they are responsible, too, that they are masters of their profession. The leaving of these men alone does not do them justice. The day may come when a better position opens up. They cannot accept another position of unlimited capacity without passing this highly technical examination. This, I claim, is an injustice. It also puts these engineers in a humiliating position; they are placed at the mercy of their employers. They cannot make demands of their employer, because they are not independent.

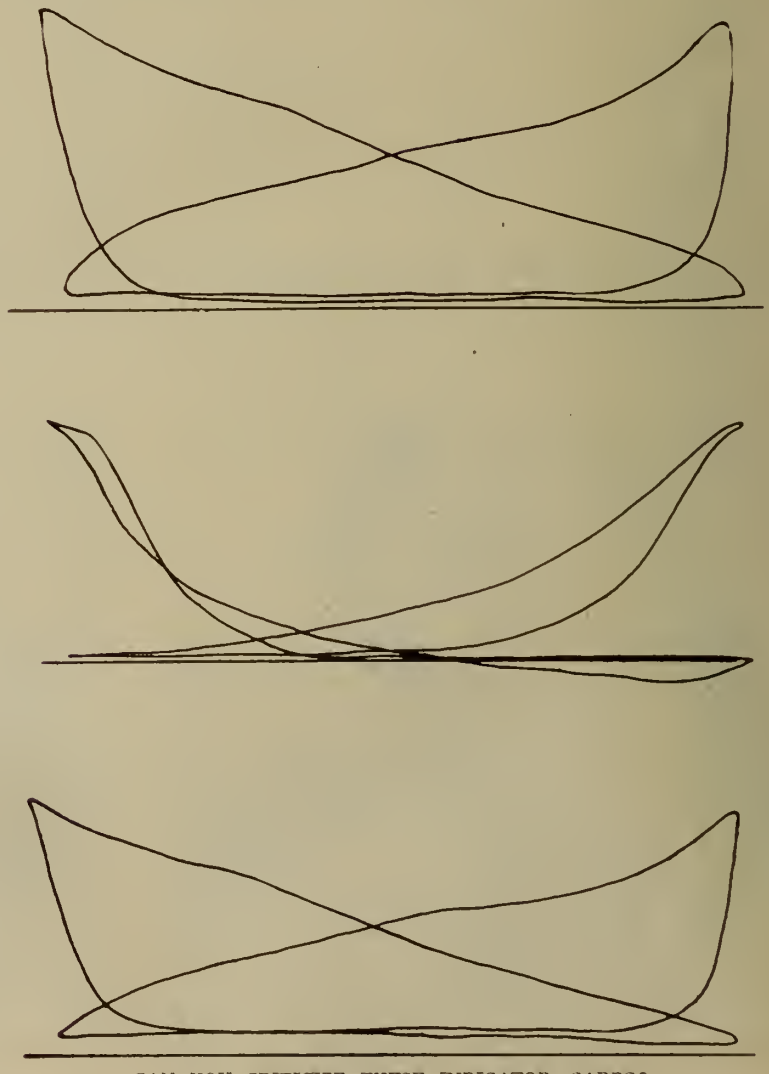
In our city one of the men who has been employed by the Government to arrange the different examinations of the different grades, told an assembly of engineers that it was not essential for a man to have all the different formulaes necessary to pass these examinations in his mind. But this is not borne out in the act. This is what it says: "In the event of any candidate being discovered referring to any book or paper, or copying, etc., he subjects himself to the penalty of failure." Now, I have set the ball rolling, let us hear from some more of the engineers.

CHIEF.

INDICATOR DIAGRAMS FOR CRITICISM

The accompanying diagrams are submitted for the criticism of POWER HOUSE readers. I would like to have some reader tell me just what trouble is present in the setting of the valves. One is taken before noon with a fair load, another is taken just before quitting with a light load, and the other one after disconnecting the clutch from the jack shaft, thus with only friction load.

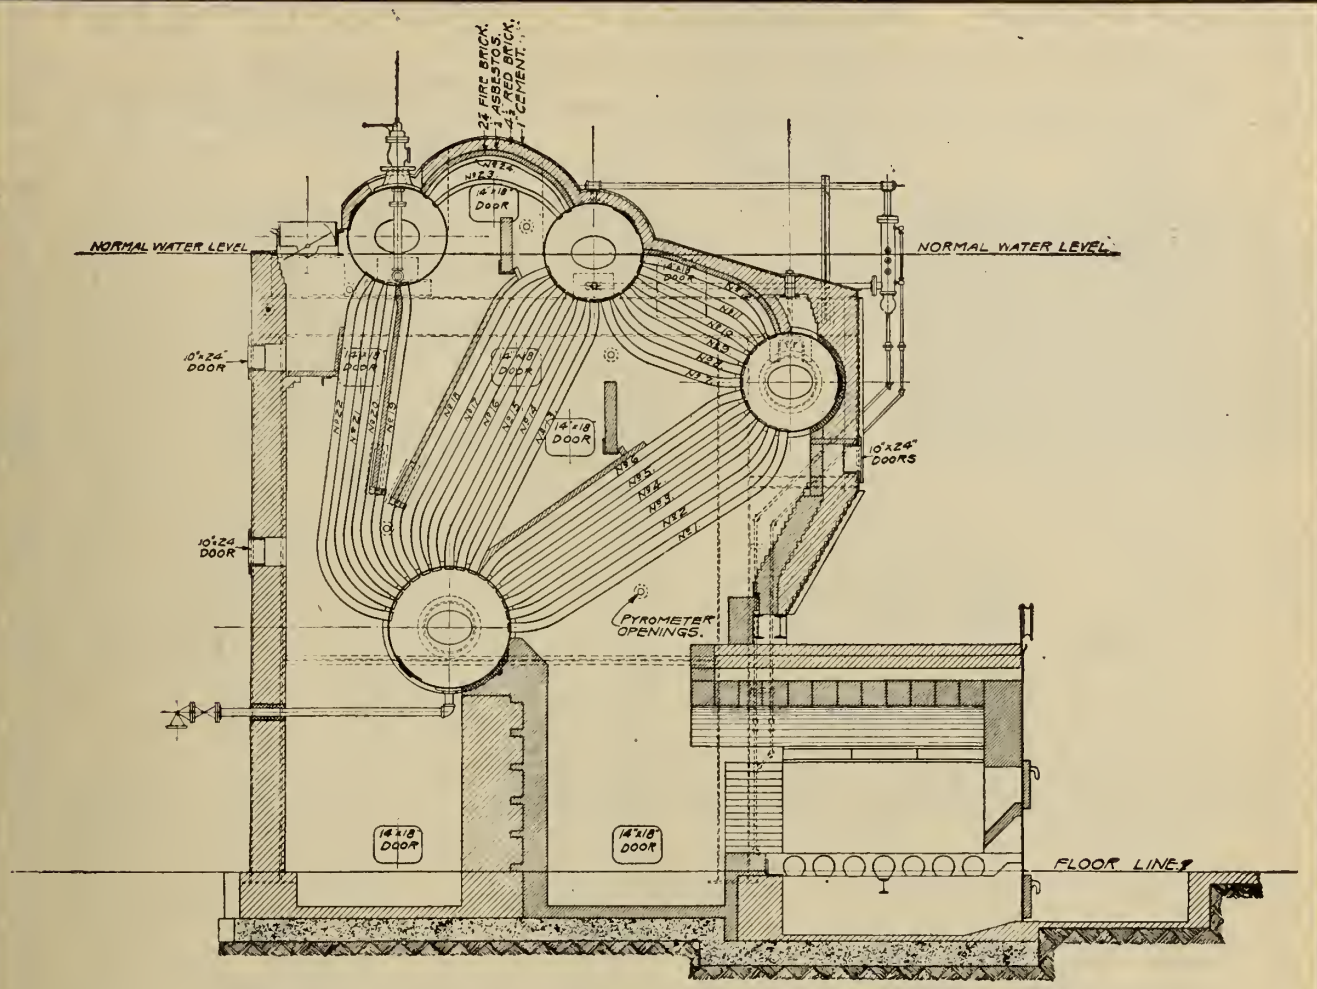
Editor's note.—We are desirous of obtaining from our readers, representative indicator diagrams for analysis and criticism. The interchange of information concerning the feature of power plant engineering is valuable in the extreme and we urge our readers to respond.



CAN YOU CRITICIZE THESE INDICATOR CARDS?

The Oil Engine Works of Canada, 29 Prince St., Montreal, will shortly move their plant to Iberville, Que., where they will occupy a portion of the plant of the Rapid Tool and Machine Company. When in Montreal the bulk of the machine work on the engines was performed in outside shops, and the assembling of the units was not all that could be desired. In their new location nearly all of the work will be carried on at the assembly plant. There is a steadily increasing demand for these engines.

R. M. Rook, who for the past five years has been associated with the Metal Thermit Corporation of New York, has been appointed general foreman of the St. Lawrence Welding Company. Mr. Rook has had a wide experience in welding work of every description, and was directly responsible for the successful repairs on what is considered the largest job yet accomplished by the thermit process. This was on the frame of a large stone machine, the weight of which was approximately 75 tons, requiring about 4 tons of thermit. Nearly seven weeks were required in preparing the mould.



Connelly (Patented) Water Tube Boilers

Made in Canada by

E. Leonard & Sons, Limited

Are of the four drum type and have 100% tube area directly in the path of circulation which not only delivers steam in abundance, but dry steam that is superheated for use at 200% to 300% with perfect safety.

A few of their good points—

Simple in design. Have no flat surfaces. Free from hundreds of joints. No hand holes at end of tubes.

Contain a tremendous volume of water, in proportion to their size. All stress due to expansion and contraction is well taken care of. Boiler tubes are so spaced that any one may be removed without moving the rest.

Designed to get the maximum horsepower in the smallest cubical space.

Can be built in units up to 4,000 horsepower.

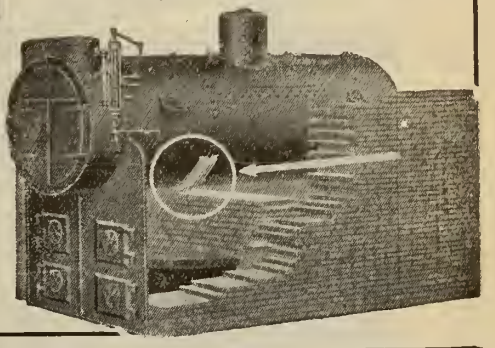
NATIONAL Boiler Girth Seam Protector

Protection means longer life and greater efficiency

If your Boiler is not Fire-cracked it eventually will be. Prevent this by putting on a National Boiler Protector. You will save cost in repairs and prolong life of the boiler. All new boilers should be protected. If your girth seam is giving you trouble at the present time, have the seam caulked up, attach one of these protectors and the seam will remain absolutely dry thereafter.



Guaranteed for one year. We make protectors for patches and all styles of boilers. For full particulars, write—

National Boiler Protector Co.
Room 24
Lombard Building
TORONTO
Main 2623

As a consequence of the large demand for electrolytic copper during the war, the price advanced very greatly and many concerns for manufacturing this product were opened in Japan. The raw material for this industry was obtained from the Chinese bronze coin, which was imported into the country in large quantities until the Chinese Government prohibited its exportation. At present the prices of electroytic and ordinary copper vary so slightly that it does not pay to manufacture the former. Copper sheet manufacturers are also hard hit by the decline in prices and some of the large concerns are suspending operations or giving up this branch of business.

C.P.O.S. and Furness Withy.—Sir Frederick Lewis, of Furness, Withy & Co., has announced the completion of an arrangement with the Canadian Pacific to supply half the tonnage required in the services to Montreal and London, and Montreal and Antwerp. These lines are known as the Canadian Pacific Joint Services. The Furness-Withy Co. have also taken over the New York and Bermuda service of the Quebec Steamship Company, and have bought the steamer "Bermudian." In St. John, N.B., they have acquired the business of William Thomson & Company, who for many years acted as the company's agents in that port.

Plate Next Year.—After completing a tour of inspection of his company's properties, President Mark Workman of the Dominion Steel Corporation has returned to Montreal. Mr. Workman states that some of the furnaces at Sydney have resumed operations. With the completion of the new ship plate mill, which will probably become a producer early in the new year, an additional demand will be made on the furnaces. "The demand for steel products," said Mr. Workman, "is improving. There is, also, an urgent need for coal the world over, and it is this branch of our operations on which we are now concentrating our attention. With our unequalled loading facilities at four ports on the Atlantic seaboard, we are in an exceptionally advantageous position to take care of export and bunker coal requirements, and we are bending every effort toward raising our output to its normal level, in order that we may meet the conditions to the largest possible extent."

SALE OF MILITARY STORES, ETC.

DRY GOODS, HOSPITAL FURNITURE, BEDDING, HARDWARE, LEATHER GOODS, JUNK, ETC.

SALES WILL BE MADE BY SEALED TENDER

Persons desiring to tender are requested to register their names and addresses with the

SECRETARY OF THE WAR PURCHASING COMMISSION, BOOTH BUILDING, OTTAWA

stating the class of goods in which they are interested, whether new or second-hand or both.

Tender forms with full details of the goods and places at which samples may be seen, will be mailed when ready to those who have registered as requested above.

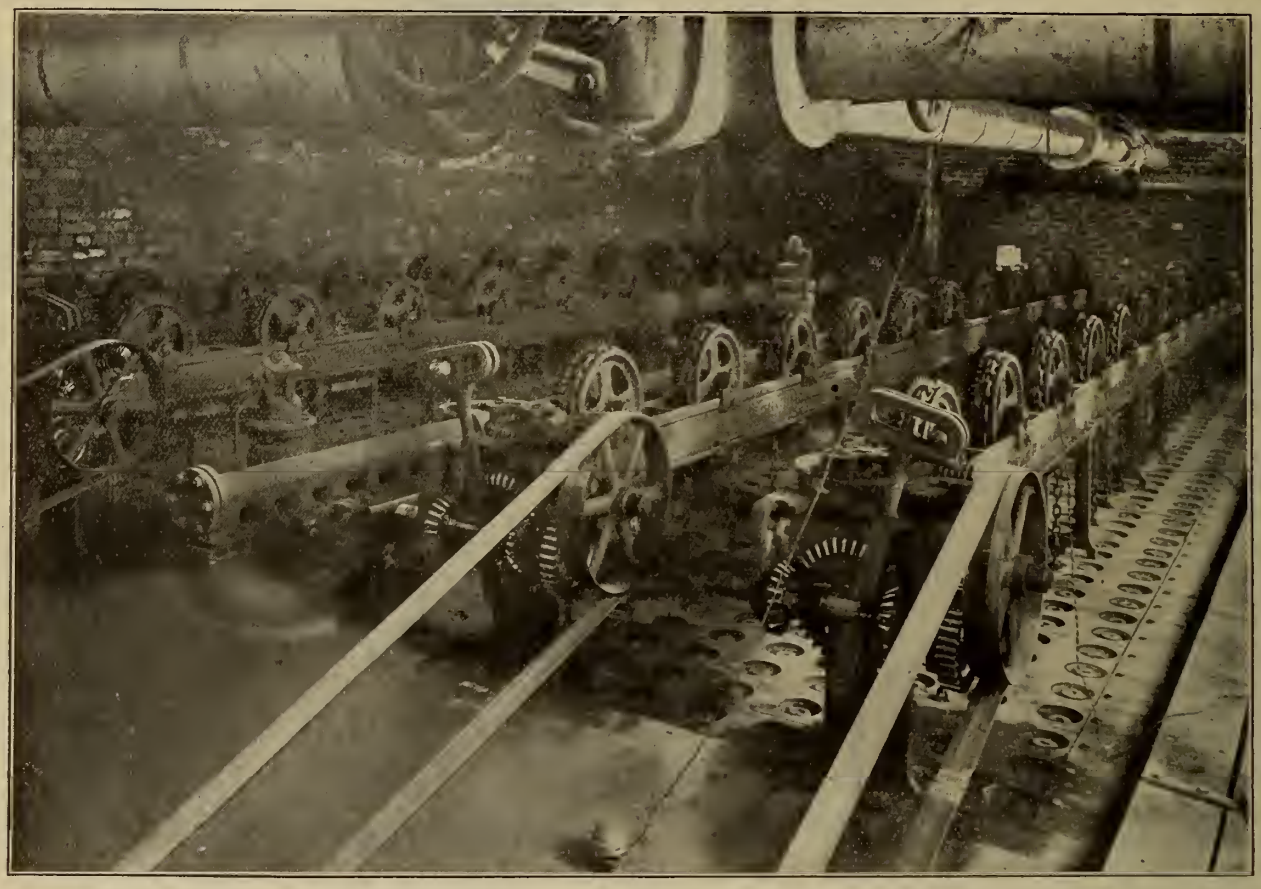
Special Terms to Hospitals, Etc.

Dominion, Provincial, and Municipal departments, hospitals, charitable, philanthropic, and similar institutions which are conducted for the benefit of the public and not for profit may purchase goods without tender at prices established by the War Purchasing Commission.

Returned Soldiers and Sailors and Widows and Dependents of Soldiers and Sailors killed in the War may obtain supplies for their own personal use and not for re-sale, through the nearest branch of the Great War Veterans' Association, who will combine individual orders and forward to the War Purchasing Commission through the Dominion Command of the Great War Veterans' Association. These services are rendered by the Great War Veterans' Association to all parties in the classes named, whether members of the Great War Veterans' Association or not.

All communications should be addressed to the Secretary, War Purchasing Commission, Booth Building, Ottawa, who will be glad to supply lists and further details to those interested.

Fuel Economy in Paper Industry



S. D. WARREN & COMPANY, CUMBERLAND MILLS, MAINE

Two of the four Green's Economizers in the above paper mill showing the scraper drive mechanism

GREEN'S FUEL ECONOMIZERS

are saving coal in every industry, not only in the United States and Canada, but wherever steam is generated by stationary boilers.

The above installation, totaling 1264 twelve-foot tubes, has just been made to replace the old Green's Economizers which have been giving satisfactory service since 1899.

Also Green's Hi-Speed Hi-Efficiency Radial Flow Fans furnish the draft for this plant.

STEEL MAKING IS GOING AHEAD NOW

Work at Sydney Commences After a Shut-Down Lasting for Some Weeks

Sydney.—Steel making is once more in progress at Sydney Mines. After a shut-down of three and a half months, a portion of the open hearth furnaces of the Nova Scotia Steel and Coal Company are once again producing ingots. The re-lining of the blast furnace has just been completed, and steel officials expect to have the furnace blown in within the next few days. Under the most favorable conditions it takes several days to relight a furnace and produce a cast, but it is not the intention of the officials to force a quick cast, as the new lining is to be given every chance to become gradually accustomed to the increasing heat pressure. The blast furnace and open hearth furnaces were closed down about the first of July and have been under repairs ever since then. The first ingots since that date were produced a few days ago. As far as could be learned winter prospects at the Scotia plant during the coming winter are fairly bright. This seems to be particularly true as regards the steel industry. The company, it is understood, have some fairly large orders in view, but have not yet closed with them. Negotiations are in progress, and unless some unforeseen obstacle arises, the contracts will shortly be completed. The situation at the collieries of this company seems to be somewhat uncertain at present. Just now three of the four collieries of the company are working every day, while the other, the Jubilee, operates from three to four days per week. Whether this situation will continue indefinitely will depend largely on market conditions.

Paul O. Abbe, 30 Broad St., New York City, have issued a condensed catalogue (F), listing specialties such as ball and pebble mills, rotary cutters, mead mills, hammer mills, bolting reels and mixers. Bolting cloth, grinders and vacuum pumps are also listed.

The Marconi Wireless Company of Canada have removed their main offices from 173 William Street (the plant location), to 11 St. Sacrament St., Montreal, in the heart of the business district.

WANTED

Representatives to handle special line of British made "Elastic Steam Jointing Cement" (for all joints) and Iron Cement for castings, etc. Exclusive territory offered parties conversant with trade. Replies treated confidential. Apply Box 151, Power House.

Don't Throw Away The Price of Two Steam Traps

That's exactly what you do every time you buy a cumbersome, complicated bucket or float type steam trap.

For at less than ONE-THIRD the cost of such traps you can buy this simple, compact thermostatic Steam Trap Sarco. This will do everything that the three-times-more-expensive float or bucket traps can do and do it BETTER.

Try out the Steam Trap Sarco. It won't cost you a cent, or obligate you in the least, to give it a thorough test in your own plant under the most difficult conditions. We will GLADLY send it for a 30 days' free trial.

We know it will MAKE GOOD.

STEAM TRAP SARCO

Does its work efficiently and promptly. Just as soon as the condensate gathers, and the sensitive but infallible expansion element opens the valve and allows the water to run off. Just as soon as the water has run off, the valve closes. No gathering of condensate in the pipes—no waste of live steam—no leaks.

Steam Trap Sarco is so compact that it can be installed in the most limited space at any point in the line, and at any angle.

It is so simple that it seldom, if ever, gets out of order. It has only one moving part. No levers, gauges, etc., to adjust or cause trouble.

Steam Trap Sarco is guaranteed for any given pressure up to 200 lbs.

Why not avail yourself of our offer to send you steam Trap Sarco for a 30 days' free trial?

At any rate, send for Booklet "J."

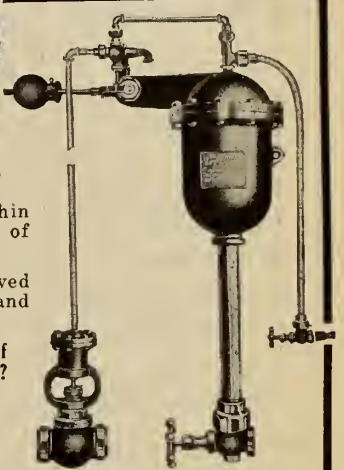
VIGILANT

Automatic
Feed Water Regulator



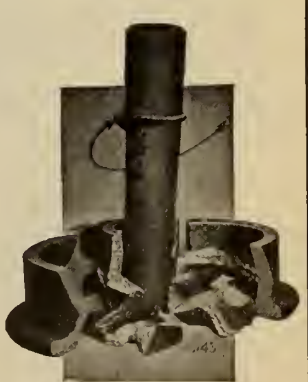
The "Vigilant" keeps water within ¼" of middle gauge regardless of load or firing.

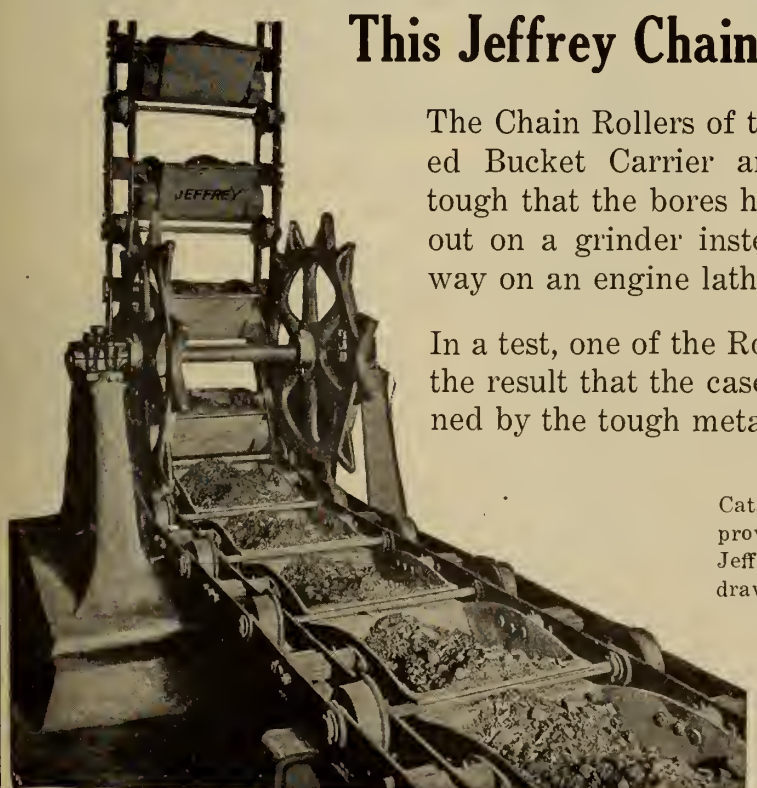
Years of service test has proved it the utmost in reliability and efficiency.

Catalogue presents many points of interest. May we send you a copy?

The CHAPLIN-FULTON MFG., CO.
8 Penn Ave., Pittsburgh, Pa

A Tool Steel Mandril Was Skinned in Breaking This Jeffrey Chain Roller





The Chain Rollers of the Jeffrey Pivoted Bucket Carrier are so hard and tough that the bores have to be turned out on a grinder instead of the usual way on an engine lathe.

In a test, one of the Rollers was split by a steel mandrel with the result that the case-hardened mandrel was actually skinned by the tough metal of the Roller.

Catalog No. 210-4 will tell you about other tests that proved that rugged dependable construction of the Jeffrey Carrier, and has many interesting illustrations, drawings, etc.

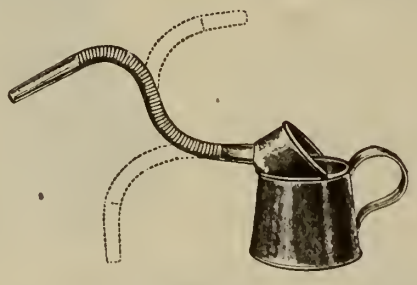
Say Good-bye to Funnels Use this "All-WAY" Oiler



Combination Filler and Funnel

This Filler eliminates the necessity of the use of a separate Funnel. With the Flexible Spout any part can be readily reached.

Saves much inconvenience and avoids dripping of oil.

If your dealer cannot supply you, write us.

We also manufacture the well-known "All-Way" Oil Can. Saves you 50% of your oil bill.

196 King St. West Toronto, Ont.

MASON
STEAM SPECIALTIES for Service

Important Points to Consider

You want steam specialties that will give you good service day in and day out, and year after year.
You want the least possible trouble.
You want the least possible repair bills.
Then you want the MASON Line. It includes:

Mason Reducing Valves (Genuine).
Mason Pump Governors.
Mason Pressure Controllers.
Bundy Steam Traps for every service.
Coppus Turbine-driven blowers.
Sims Hot Water Generators.
Sims Storage Heaters.
Sims Open Feed Water Heaters.
Bundy Oil Separators.
Ashton Gauges and Safety Valves.
Everlasting Blow-Off Valves.
Babbitt Sprocket Rims.
Stratton Steam Separators.
Reilly Multi-coil Feed Water Heaters.
Reilly Evaporators and Distillers.
Reilly Multi-screen Feed Water Filters.

New Bundy Steam Trap

REMEMBER — our salesmen are practical engineers. They sell from knowledge and experience not from catalogue.

Toronto Representative—The Arthur S. Leitch Co., 1002 Kent Bldg.

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

RALPH CONNOR

On "The New Canada and Its Needs"

RALPH CONNOR, the famous Canadian novelist, who served for several years at the front and saw the war from many angles, is convinced that Canada must be prepared to make important changes if she is to profit by the lessons of the war. He has written a series of articles embodying his views and calling vigorously on patriotic Canadians to awake to the needs of the hour. The articles, which deal with economic, social and Imperial topics, were written for MACLEAN'S MAGAZINE and the first appears in the November issue, under the title: "The New Canada and Its Needs."

Every Mother Who Lost a Son at the Front

will read with deepest feeling Nellie McClung's wonderful story, "Men and Money," which also appears in November MACLEAN'S. Mrs. McClung wrote this story with a purpose—to show the ease with which the world forgets the contribution these mothers made. But it is also a very fine story—real, human and gripping.

"The Idle Hands at Ottawa"

By J. K. MUNRO

The recent session of the Dominion House was in many respects an idle one. There was not a great deal done, so the members had a lot of time to stir up things, and the result was some hugely interesting political situations. All of which J. K. Munro tells about in his usual unsparing and tersely humorous way.

Remarkable Features of a Remarkable Number

The November MACLEAN'S is cram full of other big features—famous writers on vital subjects and everything **Canadian.** Look over this list:

Baroness Orczy.—The author of "The Scarlet Pimpernel," best seller of best sellers, is represented by a serial story, "His Majesty's Well Beloved."

Robert W. Service.—The great poet of the Yukon and the battlefront contributes a strong poem, "The Outlaw."

Basil King.—This great novelist who lives abroad contributes an interesting discussion on "Why I Remain a Canadian."

Janey Canuck.—An article on Mrs. Murphy's experiences as the first woman magistrate in the whole of Canada.

Camilla Kenyon.—A new novelist who promises to become a great favorite, tells a humorous story of adventure, and treasure, "Spanish Doubloons."

Stephen Leacock.—A humorous sketch entitled, "My Memories and Miseries as a School Master."

"Two Men and an Idea That Grew and Grew and Grew."—By Charles Christopher Jenkins.—A sketch of two remarkable and practically unknown Western Millionaires.

"A Little Bit of Chicken Feed."—By Allen C. Shore. A bright story combining love and business themes.

"The Rainbow Death,"—By Madge Macbeth. An intensely interesting detective story.

"The Search for Missing Men."—By Gertrude Arnold. An article on hospital experiences at the front by a young Canadian V.A.D.

MACLEAN'S will be Twice-A-Month

starting February 1st, next year. An important point to remember. If you want to keep up with things **nationally Canadian,** you'll have to get the MACLEAN'S Twice-A-Month habit.

Over 70,000 Canadian Families Buy

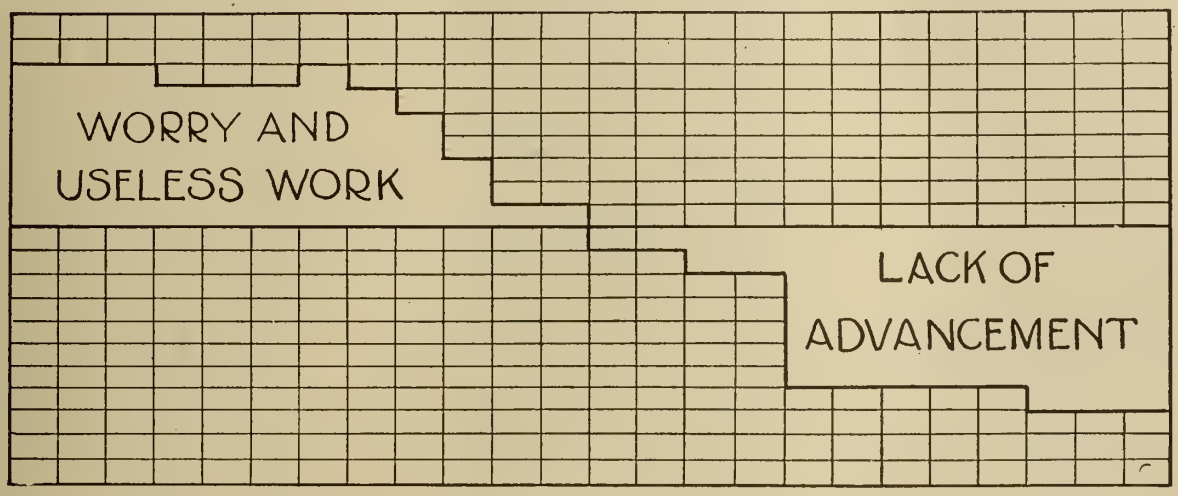
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

Canadian Association of Stationary Engineers

230 Caroline Street Hamilton, Ont.

Why Lay Up Fire Brick Again —And have the same trouble year in and year out?

The ordinary brick lining with its joints gives way under the varying furnace temperatures, crumbles and falls down. With Betson's Plastic Fire Brick you can practically eliminate this maintenance of brick work.

BETSON'S REG. U.S. TRADE MARK PLASTIC FIRE BRICK PAT. OFF.

is the pioneer and tried boiler refractory material, and has twenty years of practical experience behind it. Betson's takes up expansion and contraction internally. It is easy to lay up. It forms a monolithic lining without joints and there is nothing to work loose or fall down. It can be used for the entire boiler—furnace, door arches, rear arches, baffles, bridge walls, etc.

Let us quote you on Betson's Plastic Fire Brick for your boiler needs. Or send for our practical booklet to-day.

"Beaver" Globe Valve
Iron body, bronze mounted.

Here Is One Of Its Strong Points

The improved joint between the body and yoke and the machined faces of the double spigot prevents any possibility of the gasket blowing out.

"Beaver" Valves Have Enjoyed a Remarkable Success For Over Eight Years

During this period we have not received a single complaint and there has been a wonderful increase in production.

BEWARE OF IMITATIONS

When ordering valves make your specification read "Morrison Beaver Valves" and you'll take a precaution that insures you a valve of proven reliability, long life and safety.

Write for full particulars.

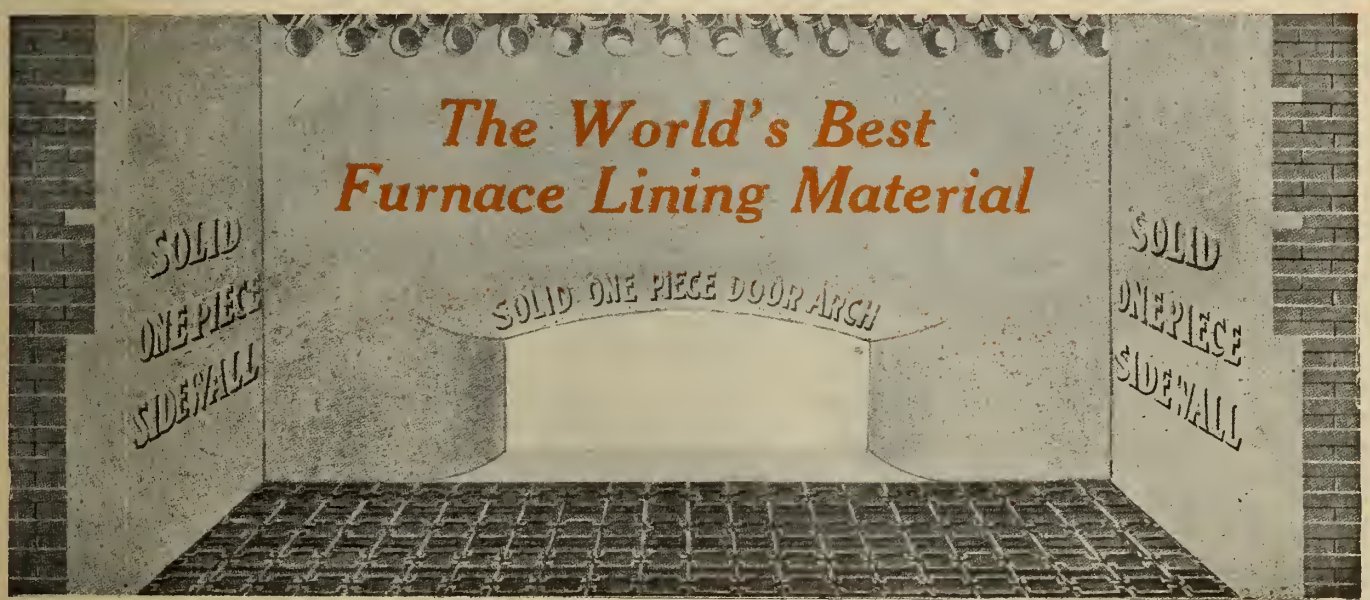
POWER HOUSE

A semi-monthly newspaper devoted to the Generation, Transmission, and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery.

Published by The MacLean Publishing Company, Limited, 143-153 University Ave., Toronto

MONTREAL: Southam Bldg. LONDON, ENG.: 88 Fleet St., E.C. WINNIPEG: 1103 Union Trust Bldg.

Vol. XII.—No. 20. Publication Office, Toronto—December 5, 1919 Published Semi-Monthly $1.00 per Year



Sketch above represents the fire box of a water tube boiler lined with PYRO PUTTY.

PYRO PUTTY TRADE MARK REG U S PAT OFF

FIRE BRICK IN PUTTY FORM

Makes a More Durable Furnace Lining Than is Possible With Fire Brick

Minimizes Upkeep Expense. No Joints to Cause Air Leaks.

PYRO PUTTY comes to you in a stiff, moist, pliable, "ready-to-use" condition.

Simply pound PYRO PUTTY on with a mallet, smooth it off with a trowel and you have furnace lining that is far more durable than a fire brick lining.

"A few barrels of Pyro-Putty should be part of the emergency equipment of every steam power plant"

Repairs to your present fire brick linings can be made at a considerable saving of time and at less expense than would be possible with standard fire bricks.

Simply clean out the breaks in the walls, pound in PYRO PUTTY with a mallet, smooth it off with a trowel and you'll have a patch that will outwear the rest of the furnace lining. Order a few barrels NOW.

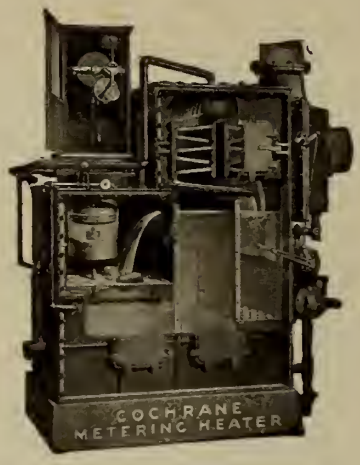
Write to-day for further information and prices

PYRO PRODUCTS COMPANY

P.O. Box 685, Toronto, Ontario

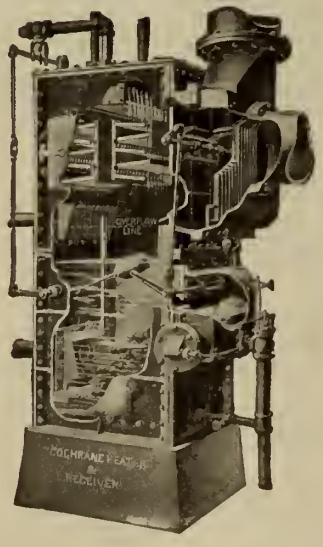
COCHRANE
COAL SAVERS

The Cochrane Oil Separator saves coal by rendering the exhaust steam useful for heating, drying and other purposes.



The Cochrane Metering Heater saves coal by heating the feed water and helps save coal by telling whether or not the plant is being operated economically.

The Cochrane Multiport Back Pressure Valve saves coal by preventing leakage of exhaust steam and by making it easy to adjust the back pressure whenever desired. The Cochrane Oil Separator saves coal by rendering the exhaust steam useful for heating, drying and other purposes.



The Cochrane Open Feed Water Heater saves coal by utilizing exhaust steam to heat the feed water; 1% saving for each 11° F. rise.

Canada is Saving Many Thousand Tons
of Coal Per Year by Using Cochrane Heaters

Here are the figures:

The horsepower of Cochrane Heaters in use is about 10,000,000 boiler horsepower.

The corresponding amount of coal burned is 35,000,000 lb. per hour.

Considering an average of 10 hours' operation per day, 300 days per year (many heaters run 24 hours per day, 365 days per year), this amounts to 105,000,000,000 lb. of coal per year, or 50,000,000 tons, worth at $5.00 per ton, $250,000,000.

The saving due to the use of Cochrane Heaters is 1% to each 11° F. rise in temperature. On the average, the water is raised from 100° F. to 210° F. using steam at atmospheric pressure, 10% or a saving of 10%. Cochrane Heaters are thus saving about $25,000,000 per year, which is vastly more than the heaters cost.

In addition, Cochrane Oil Separators are saving millions of tons of coal by purifying exhaust steam so that it can take the place of live steam in heating and drying coils, low pressure turbines and industrial processes.

Sorge-Cochrane Hot Process Water Softeners are saving millions by keeping scale and corrosive substances out of boilers and thus saving expense and labor in cleaning boilers, and for new tubes and other boiler repairs.

Cochrane Metering Heaters are also telling hundreds of steam-plant owners, managers and operators how much they are gaining in economy by using different coals, different methods of firing, different methods of controlling the draft, stopping up air leaks in boiler settings, cleaning soot and scale from heating surface, etc. The total gains realized in this manner often amount to 25% or more.

Our engineering department has given hard study to fuel economy for over 25 years. It will be glad to aid you with suggestions if you will describe your present boiler feed water heating, softening, or metering arrangements, the amount of exhaust steam you have available and what you are using it for.

Ask for a book on "The Profitable Utilization of Exhaust Steam."

BOILERS

FOR POWER AND HEATING PURPOSES

You will find Waterous Horizontal Return Tubular Boilers in the largest industrial and municipal power plants in the country. There are reasons for this. They are economical of fuel, carry a big reserve steam pressure for use in emergencies, can be used with hard and dirty water, and are readily cleaned and easily taken care of. They cost little new; their upkeep and maintenance expense is negligible.

Waterous Horizontal Return Tubular Boilers are built in all sizes from 40 inches by 10 feet to 72 inches by 18 feet. Most standard sizes are carried in stock. If we cannot supply you at once from our yards we can turn out your order for you in quick time. On the next boiler you need let us quote you prices and delivery.

POWER HOUSE, December 5, 1919, Vol. XII., No. 20. Published semi-monthly at 143-153 University Ave., Toronto, Canada. Subscription price in Canada, $1; in United States, $1.50. Entered as second-class matter at the Post Office Department, Ottawa, Canada. Entered as second-class matter July 1, 1912, at the Post Office at Buffalo, under the Act of March 3rd, 1879.

PLAY SAFE

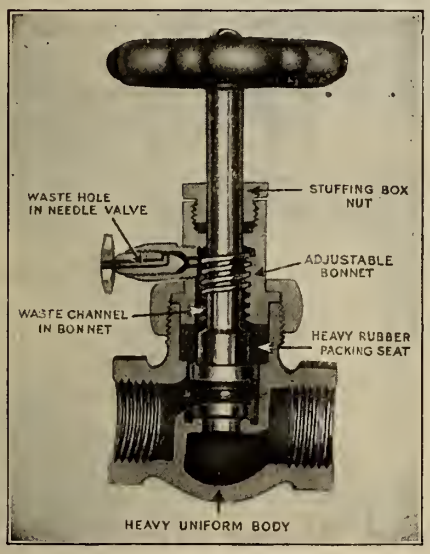

Plate A 840
Jenkins Disc Globe Valve

The whole steam system will be dubbed wrong if a faulty valve is installed, no matter how good the other fittings are.

The sanitary engineer cannot afford to have his good work reflected upon, by so small, yet so important, a factor of the work.

Make sure that the valve is right above everything else.

"Emco" valves are fitted with special high heat resisting "Radium" discs which last a lifetime.

They are registered in all provinces of the Dominion, our ordinary line being approved for 175 lbs. working pressure. All goods are thoroughly inspected and tested before they leave our factory.

Send for our catalogue. Specify "Emco" valves from your jobber or order direct from us.

Garlock Packings

Have you ever considered the loss in engine efficiency due to excessive friction on piston and valve rods caused by the use of inferior and poorly lubricated packing?

A horse power easily can be absorbed at the stuffing box and, when considered in dollars and cents at the coal pile, the loss would pay for a high class packing many times over.

Garlock packings are designed to meet every condition of service.

Asbestos—

the only rock on which plants thrive

INDUSTRY thrives most where waste is least. And since the development of Asbestos has gone hand in hand with the saving of heat, power and friction, this mineral of wonderful qualities has played an important part in Industrial Conservation.

It is the base of all efficient heat insulation—the necessary *other* 15% in 85% magnesia.

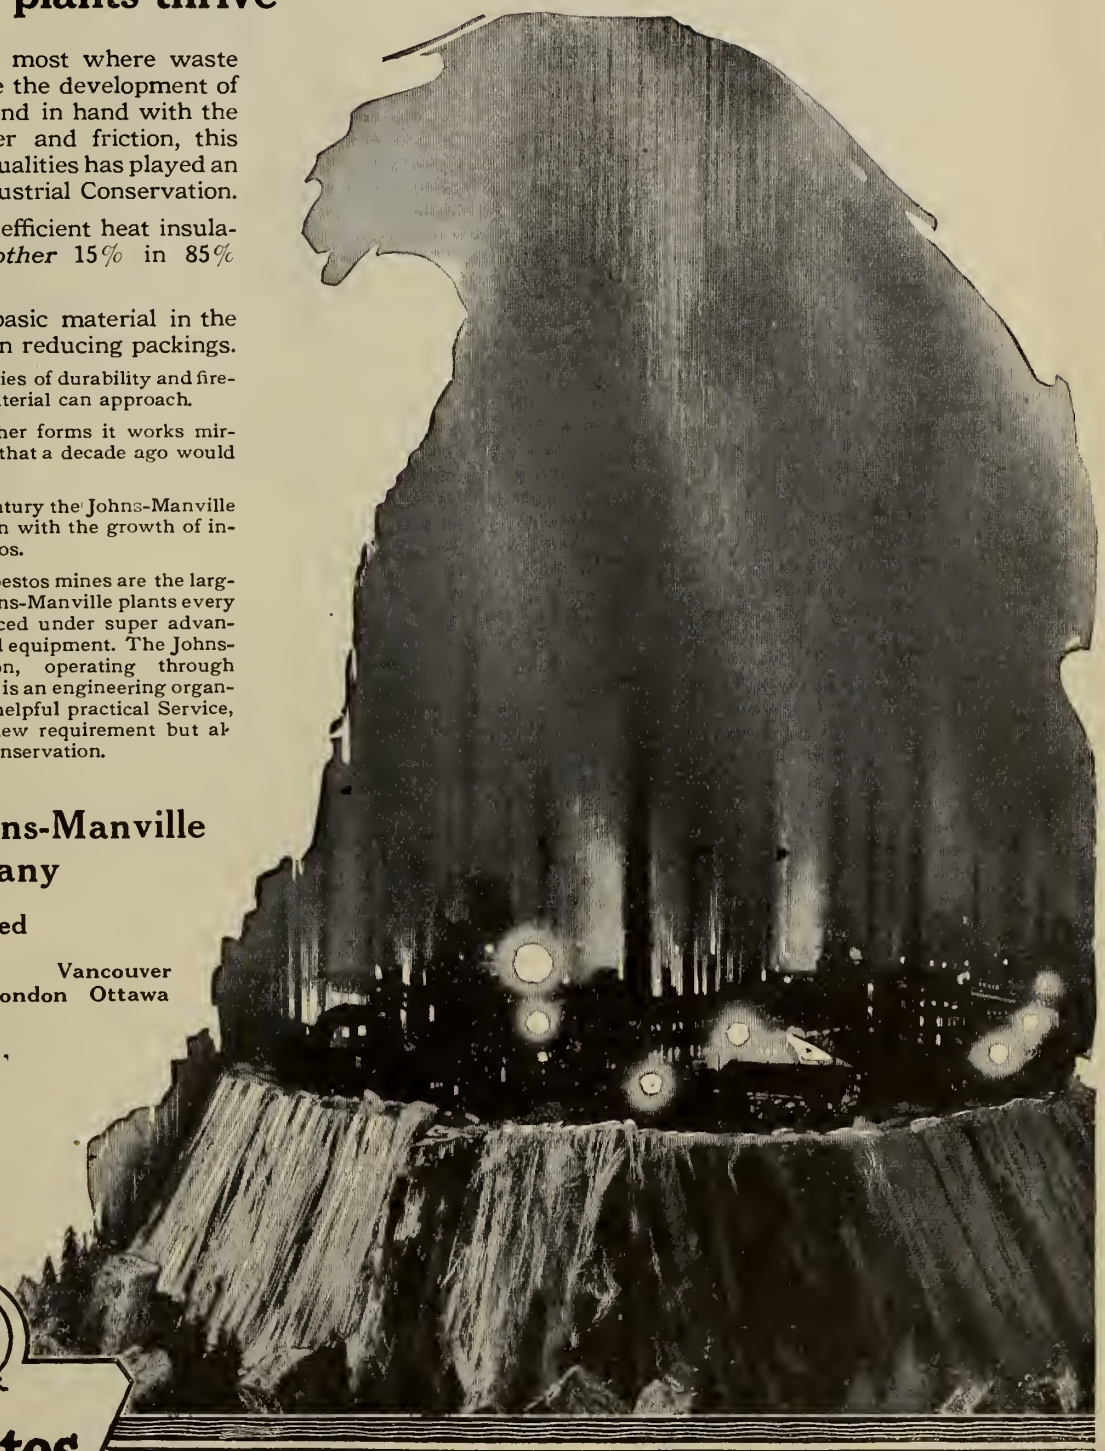
It is, as well, the basic material in the most efficient of friction reducing packings.

As roofings it has qualities of durability and fire-resistance that no other material can approach.

And in innumerable other forms it works miracles of industrial economy that a decade ago would have seemed impossible.

For more than half a century the Johns-Manville Company has steadily grown with the growth of industrial demand for Asbestos.

The Johns-Manville asbestos mines are the largest in the world. In the Johns-Manville plants every Asbestos product is produced under super advantages both of experience and equipment. The Johns-Manville sales-organization, operating through branches in all large cities, is an engineering organization as well, carrying a helpful practical Service, that varies to meet each new requirement but always has for its object—Conservation.



Canadian Johns-Manville Company

A Short Route to Increased Production

Efficiency of equipment is the shortest route through which you can increase production, and offset the high cost of material and labor.

Your first consideration should be to get the most out of the power that you are paying for.

Dominion Friction Surface Belting

will transmit as near one hundred per cent. of each power unit as can be transmitted by a belt.

During more than fifty years of experience in belt building for power transmission, we have perfected a special friction compound that acts not only as a water-proofing, as a vulcanizer to the fabric plies of the belt, but enables Dominion Friction Surface Belting to take a grip on the pulleys that practically eliminates all power waste.

Our engineers will be glad to show you, without charge, how Dominion Friction Surface Belting shortens the route to increased production, thereby lowering *your* manufacturing cost. Their services are available through our nearest Service Branch.

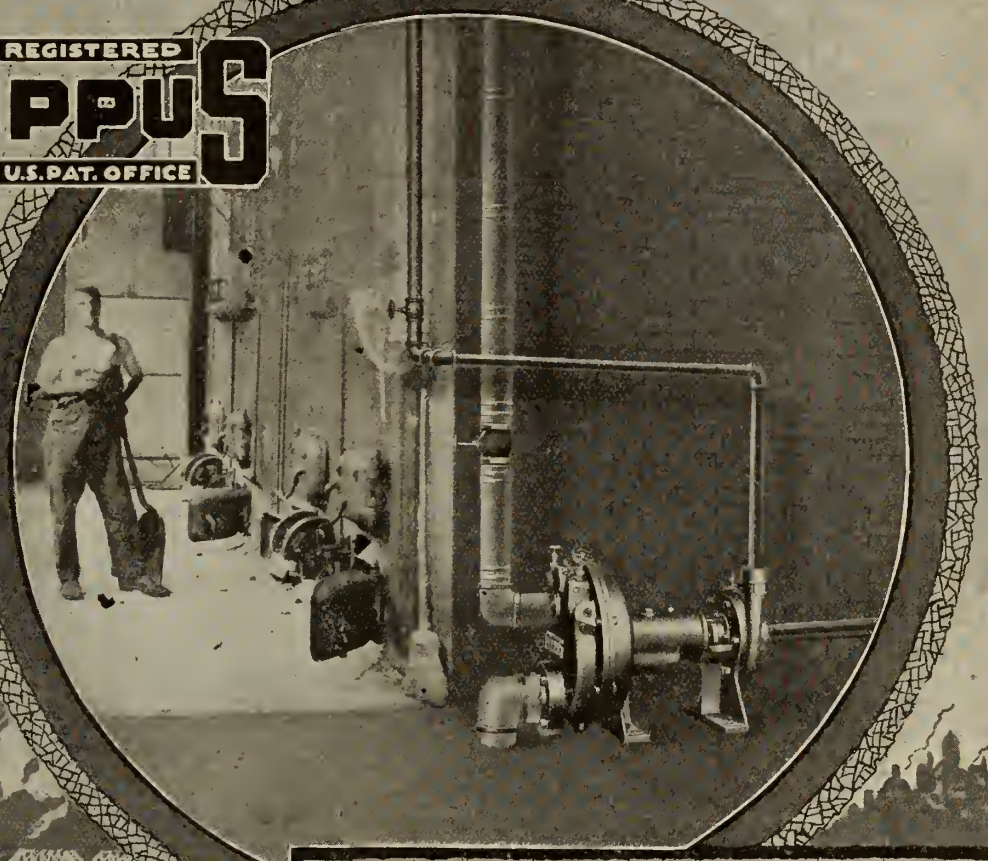
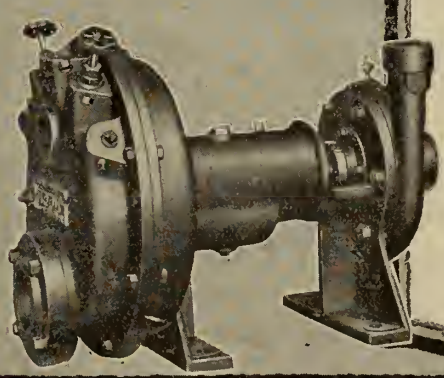
COPPUS
U.S. PAT. OFFICE





This Dependable Boiler Feeder for Your Power Plant

Possesses These Distinct Advantages:—

Simplicity of construction.
Steady feed without pulsation.
Easily controlled feed capacity.
Exhaust steam free from oil.
Less floor space required.
Lower upkeep—less attention required.
Higher Steam Economy.
Longer life—less depreciation.
Single unit construction.
Completely built in our plant.
Especially designed for the purpose.

Our Engineering Department will gladly recommend the size best suited to your particular requirements. Write to-day for Catalog H-20, and let us show you how —*"COPPUS Equipment can save you money."*

COPPUS Centrifugal Turbo FEED PUMP

LINDE

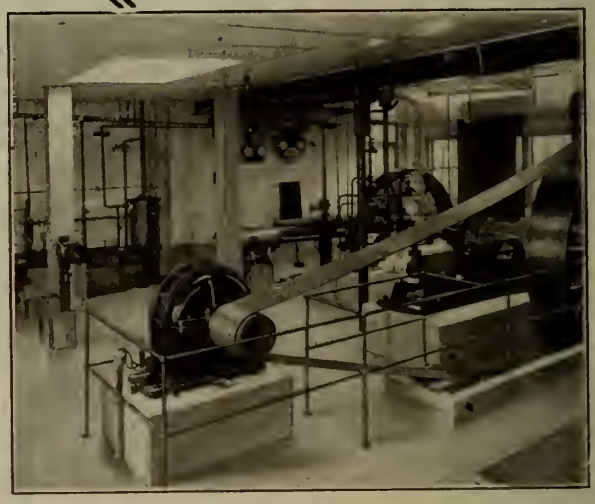
REFRIGERATING AND
ICE MAKING MACHINERY

Everything for Refrigerating and Ice Plants, large or small

Mechanical refrigeration scientifically applied means increased returns to the user. Increase your profits by installing LINDE system in place of unsanitary methods. LINDE (New) Vertical Enclosed Type Machines offer the most modern improvement and convenience for small plants from 1 to 30 tons. The large horizontal frame type guarantees unequalled service to users whose heavy demands call for loads up to 300 tons.

LINDE machines represent Quality and Service!

100-ton plant in operation.



Our engineering staff is at your service. Designs, specifications and estimates on request.

Every Part of Every FRICK INSTALLATION Must Be Perfect in order to maintain

FRICK SUPERIORITY

That is why Frick Refrigerating and Ice Making Equipment proves a profitable investment wherever installed.

The entire Frick line, from the smallest to the largest plant, from the smallest part to the largest part in each plant, is designed to meet our strict standard of Durability—Efficiency—Economy. Every part must be perfect in order to maintain the well-known FRICK Superiority.

Therefore, when you purchase FRICK Equipment you are assured of perfect service regardless of the unforeseen overload demand that might be placed on it sometime—assured of continued operation without danger of breakdowns in the midst of a busy season—assured of economical operation at all times—and a long life. Frick Equipment has been standing up under the above conditions for nearly a half-century, day after day, year after year, under the most severe conditions.

You can't go wrong when you specify "Frick Equipment." **Catalog on request.**

Ask for a copy of our List of Users covering 48 pages of satisfied customers—also your copy of Ice and Frost.

Corkboard that Is *All* Cork

One important thing to be observed in the manufacture of superior corkboard is the use of **clean cork only.** Nonpareil Corkboard, known to refrigerating men everywhere for its unique service records, is made of the best cork waste available, practically all of which is obtained from the plants operated by the Armstrong Cork Company in this country and abroad. By thus going back to the sources of supply, control over the quality of the raw material is assured.

Pile to the left, cork before being cleaned. Centre pile, screenings removed in the cleaning process. Pile to the right, clean cork—the only kind used in Nonpareil Corkboard.

There are two reasons why dirt should be scrupulously guarded against in the manufacture of corkboard. First: Foreign matter reduces the insulating efficiency of the finished board. Second: If the natural gum binder gets impregnated with dirt, it cannot perform its function properly, and the result is impaired durability.

Examine a sample of Nonpareil Corkboard critically. Break it in two and look at the fractured surface. You will find it to be clean and of uniform quality throughout. For all dirt, dust and fine particles were removed from the raw material before it was baked.

If you want corkboard that is **all cork** and **good cork,** insist on "Nonpareil."

Nonpareil Corkboard Insulation

For Cold Storage Rooms

Many owners, managers and superintendents of refrigerating plants have found answers to difficult questions in the 152-page book "Nonpareil Corkboard Insulation." Do you own a copy? If not, let us send you one. There is no charge for it.

MECHANICAL REFRIGERATION

SAVES MONEY ∴ HELPS BUSINESS

"We wish to express our satisfaction with your plant, which in the past several years has saved not only money and labor, but proved a business asset as well," writes one of our customers.

Here is the whole story in a few words. No addition to your business offers more certain returns on the investment than MECHANICAL REFRIGERATION.

If your business is lagging, it can be improved by the use of MECHANICAL REFRIGERATION. If your business is good, it can be made better by installing a YORK REFRIGERATING PLANT.

Write to-day for information and prices.

There Is Only One Plastic Fire Brick

COMES IN THE YELLOW-TOP BARREL

Besides new work or complete remodeling, Betson's Plastic Fire Brick has found wide favor for use in temporary repairs to ordinary brick linings on water tube and horizontal return tubular boilers. Repairs with Betson's frequently make it possible to operate furnaces for long periods till there is opportunity to shut down the boiler, when the separate bricks can be completely replaced with a one-piece furnace lining that has no joints.

PUT YOUR OIL STORAGE PROBLEMS UP TO BOWSER ENGINEERS

ESTABLISHED 1885

Photographs of Oil Room Before and After Installing Bowser Equipment.

Photographs of Paint Room Before and After Installing Bowser Equipment.

Planning an Oil Storage System involves important details, easily overlooked by the inexperienced. Bowser service will suggest the proper system for your oils which when in operation, will bring almost unbelievable improvements in shop conditions, safety and saving.

The illustrations shown here give a fair example of what a Bowser Oil Storage and Distributing System does for the average business, large or small. There is some type of Bowser Storage Equipment suitable for your oil handling requirements.

Ask us to make a survey of your present needs. It will show you what you can expect a Bowser Oil Storage System to save you in floor space, oils, time, labor and money. This does not obligate you to buy Bowser equipment, and you will receive valuable information from such a survey.

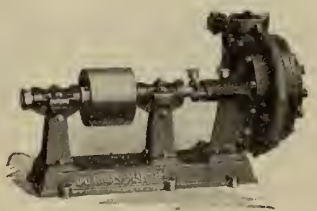
AMERICAN-MARSH PUMPS

SIMPLE RELIABLE EFFICIENT

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.

The line also includes—

Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

The Early History of the Steam Engine

The History of the Steam Engine May be Traced Very Far Down the Vast Avenues of Time. An Account is Given of the Development of This Prime Mover Up to the Time of Watt

By JOSEPH F. HEFFRON

IT is difficult at any time to determine the effect of any single invention on the welfare and progress of the human race; and the problem becomes doubly difficult where inventions of the first rank become crowded upon each other in rapid and bewildering succession, as they have in our own age. But notwithstanding these difficulties, when we look backward from our day, upon the progress of civilization, we are forced to the conclusion, that in the steam engine we have a central object without which, many of the notable achievements in the arts and sciences would have been quite impossible.

When in retrospection we sweep over the history of the world from the time when the Egyptians and Babylonian civilizations were at their height, and attempt a classification of the stages of progress in the mechanical arts during the intervening period, we remark a very significant fact. No great revolutionary invention disturbed the unbroken calm that prevailed throughout the world during the long centuries of pre-Christian antiquity, and in fact, this lack of development of practical mechanics upon which the outward evidences of our Occidental civilization in great measure depends, continued well into the middle ages of our newer era.

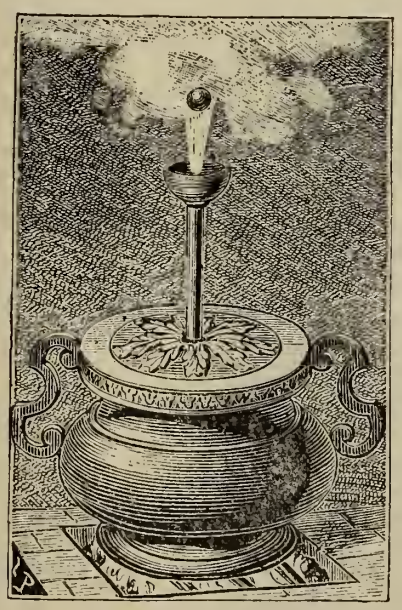

FIG. 1—HERO'S EOLIPILE.

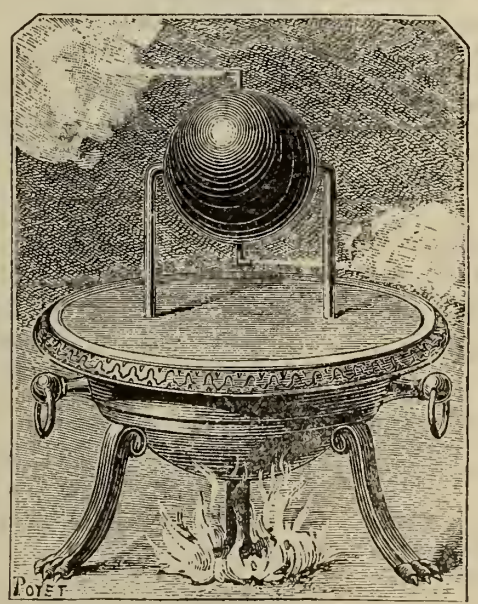

FIG. 2—HERO'S WHIRLING EOLIPILE.

The invention for which was reserved the honor of ushering in a new era was in effect a development of the eighteenth century, and did not come fully into its heritage until the early days of the nineteenth century. The invention was the application of steam to the purposes of mechanics. When this application was at last made in a practical way, a gap was crossed that was as wide as that which separated the Stone Age from the Age of Metal, and with the utilization of steam for mechanical purposes, the epoch in which the world was living when recorded history began, was brought to an abrupt close, and a new era, the Age of Steam, was ushered in.

The Earliest Known Experiments With Steam

The possibilities of the production or utilization of power from the forces of nature was but little understood by the ancients. Air as a motive power was doubtless first used through the application of sails to boats. The Phoenicians used a simple form of sail, and their example was probably followed by all the maritime peoples of subsequent periods. But even to the Phoenicians, the sail was a comparatively unimportant accessory to the galaxies of oars, which formed the chief motive power of their maritime vessels. The introduction of sails of various types adequate to propel large ships, and capable of adjustment for taking advantage of winds from almost every quarter of the compass, was a development of the Middle Ages.

It is doubtless a fact, that the existence and use of slave labor in the times referred to, made it scarcely worth while for man to tax his ingenuity in the invention of machines, since so efficient a machine provided by nature was procurable with but little expenditure of effort.

The properties of air and water were nevertheless studied at an early date by various mechanical philosophers, at the head of whom were Archimedes, the Greek mathematician and mechanician (287 B.C.), and the famous Alexandrian, Ctesibius, whose investigations are to some extent known to us through the publications of his pupil, Hero. We know little more of Ctesibius than that he lived in Alexandria, probably in the first half of the second century, B.C. His antecedents, and the place and exact time of his birth and death, are quite unknown to us. Neither are we quite certain as to the precise range of his studies or the exact number and character of his discoveries.

Of a number of the books published by Hero through which the record of the master's inventions were preserved to posterity, only one has been preserved. This work is known as "Hero's Pneumatics," and it is so interesting that it makes us doubly regret the loss of its companion volumes. For, had the remaining volumes been preserved, we should doubtless have a far clearer insight than is now possible, into some, at least, that exercised the minds of the ancient philosophers.

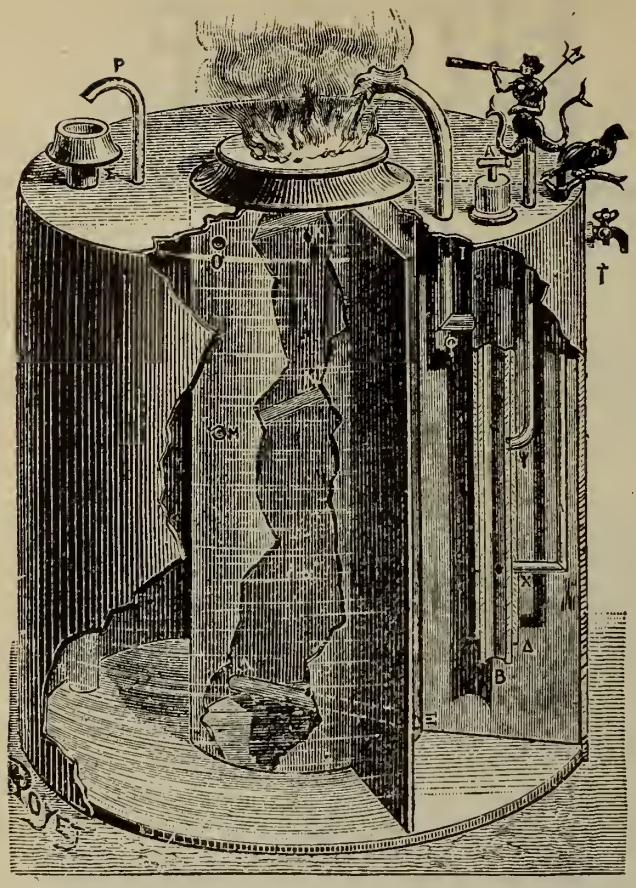

FIG. 3—HERO'S TUBULAR BOILER. SHOW OF ORNAMENTATION, ETC, THIS IS ONE OF THE EARLIEST TUBULAR BOILERS.

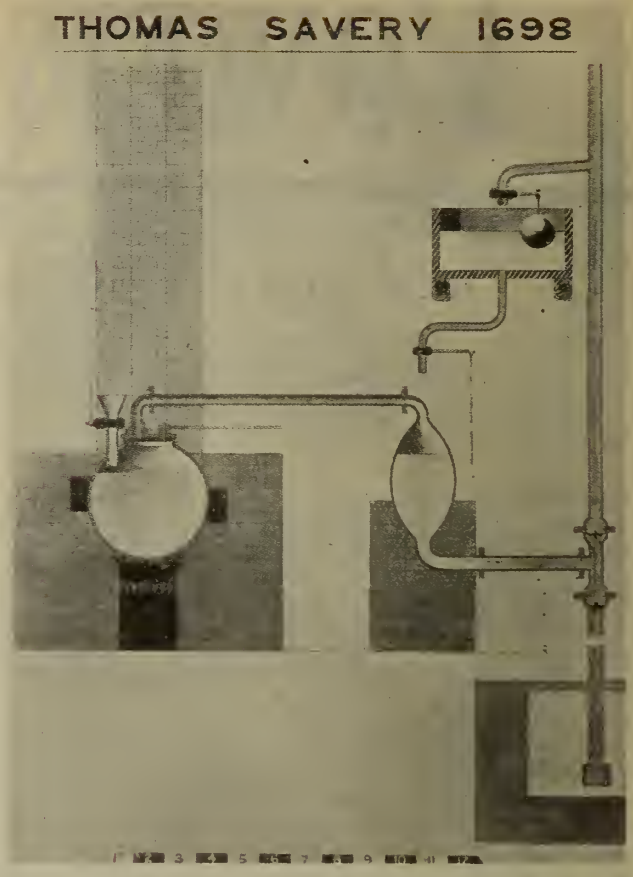

FIG. 4—THOMAS SAVERY'S STEAM ENGINE. THIS ENGINE UTILIZED THE EXPANSIVE FORCE OF STEAM AND THE SUCTION PRODUCED BY CONDENSATION TO RAISE WATER.

The contents of the "Pneumatics" as the name implies, are chiefly concerned with the study of gases, but it tells us also of certain studies in the dynamics of water, and of the invention of several pieces of apparatus that to the historian of science are of the greatest interest.

The First Record of a "Heat-Engine"

Among the devices in the "Pneumatics," we find the earliest mention of "heat-engines," and in this early work we find also the genesis of the tubular boiler and the Papin cock which was replaced in the more modern product by the long D-valve.

A literal translation of a passage from the "Pneumatics" having reference to the earliest known apparatus utilizing steam as motive power, the "eolipile" reads as follows:

"Balls may be held in the air by the following method: Fire is lighted under a boiler that contains water and is closed at its upper part. From the cover starts a tube which rises vertically, and at the extremity of which a hollow hemisphere is in communication with it. On placing a light ball in this hemisphere it will happen that the steam, on rising through the tube, will raise the ball in such a manner that it will remain suspended in the air."

Figure (1) shows a cut of the apparatus which is borrowed from a manuscript of the "Pneumatics" dating back to the Renaissance. The boiler, however, should have been placed over a fire-place which, obviously, was necessary to make the apparatus work.

Figure (2), taken from the same source, shows a view of Hero's "whirling eolipile." Here the same kind of a boiler is used. One of the two tubes bent at right angles, conducts steam into the hollow sphere which they support, and upon the escape of the steam from the interior of the hollow sphere through the smaller bent tubes facing tangentially in opposite directions at opposite ends of a diameter perpendicular to the axis, the sphere itself is caused to revolve by reaction from the escaping steam.

It does not appear that Hero had any thought of making practical use of this steam engine. It was regarded merely as a curious toy—nothing more. Yet, had not the age that succeeded that of Hero been one in which inventive genius was dormant, someone must soon have hit upon the idea that this steam engine might be improved and made to serve a useful purpose for man. As the case stands, however, there was no advance made upon the steam motor of Hero for almost two thousand years. And, indeed, when the practical application of steam was made, towards the close of the eighteenth century, it was made probably quite without any reference to the experiments of Hero, though knowledge of his toy may perhaps have given a clue to Watt or his predecessors. In recent time there has been a tendency to give this steam engine of Hero something more than full meed of appreciation. To be sure, it marked a most important principle in the conception that steam might be used as a motive power, but, except in the demonstration of this principle, the mechanism of Hero was much too primitive to be of any real importance.

Hero's Tubular Boiler

But there is another mechanism described by Hero which is of even greater interest to the scientific historian than is Hero's "whirling eolipile." This is known as Hero's "tubular boiler."

Figure (3) shows a sectional view of this boiler, and it also shows the early form of the Papin cock. In the centre we have the fireplace in the shape of a vertical cylinder, beneath which was placed an air vent—which is not shown in the illustration—around the cylindrical fireplace is the boiler, also cylindrical in form, and filled with water. Several tubes, such as O K and M N, place its various parts in communication with each other by passing through the fireplace, thus increasing the heating surface of the apparatus.

The cock T, permits the drawing off of hot water, while the funnel serves to introduce cold water into the boiler through the tube reaching to the bottom of the latter. The bent tube P, is used to permit the escape of air when water is placed in the boiler, and also served to permit the escape of steam, thus eliminating the possibility of an

ejection of water through the funnel when the apparatus was placed in operation.

In his text, Hero tells us that this tube debouches in the interior of the funnel and is therefore not easily perceived, as it is shown in the illustration for sake of greater clearness. It will be seen that there is in the boiler an angular shaped compartment formed by two vertical plates which do not permit the water to enter the compartment they form. This compartment is designed for the purpose of causing the different figures on top of the apparatus to operate, which result is obtained through the play of the steam and the several way cocks before mentioned. In the compartment will be seen two concentric tubes which are capable of revolving with slight friction one within the other. The external tube is fastened to the upper side of the boiler, and traverses it. In this tube are three apertures, each located at a different level and communicating, through smaller tubes, with the figures which are placed on top of the apparatus. The internal tube, A B, being open at its lower part, thus communicates with the interior of the angular compartment, but is closed at its upper part, which latter debouches above the upper surface of the apparatus and may be manipulated by the handle, A. This internal tube is also supplied with three apertures placed at the same level as the apertures in the external tube, but differently placed, so that when the tube, A B, is given a rotary motion by means of the handle A, one of the openings in the internal tube is brought into opposition with an aperture of the same level in the etxernal tube, and the smaller tubes referred to, communicating with the interior of the bodies of the different figures cause them to perform their various duties.

To operate the appliance, the tube A B is removed and a little water is placed in the angular compartment. This water passes into the tube A E (which passes under the fireplace and is closed at the side opposite to its aperture E,) and is converted into steam. When the tube A B has been returned to its place, it will be seen that the steam may be passed at will by turning the handle A, into the body of the bird, making it to warble, or into that of the triton, causing his trumpet to blow, or finally, into the body of the serpent, which will hiss as it blows into the fire, thus quickening the flames. The effect that the operation of this curious contrivance would have upon the credulous minds of an early and uninstructed audience can perhaps best be left to the reader's imagination.

Beginnings of Modern Discovery

Such sporadic experiments as these and of still later times, such as those conducted late in the fifteenth century by the great Italian, Leonardo da Vinci, have no sequential connection with the story of the evolution of the steam engine, but are simply of interest since they show that man had wrestled through long ages with a problem that was later on to be solved in a comparatively short space of time.

The experiments which led directly to practical achievements were not begun until the seventeenth century. In the very first year of that century, an Italian named Giovanni Battiste della Porta published a treatise on pneumatics, in which the idea of utilizing steam for the practical purpose of raising water was expressly stated. The idea enunciated by this inventor was put into effect in 1624 by a French engineer and mathematician, Solomon de Caus. He invented two different machines, the first of which required a spherical boiler having an internal tube reaching nearly to the bottom, a fire beneath the boiler produced steam which would force the water in the boiler to a height proportionate to the pressure obtained.

In the other machine, steam is led from the boiler into the upper part of a closed cistern containing the water to be elevated. To the lower portion of the cistern a delivery pipe was attached so that water was discharged under a considerable pressure. This arrangement was precisely similar to an apparatus employed by the Greek engineer Hero in various of his fountains, as regards the principle of expanding gas to propel a liquid. An important difference, however, consists in the fact that the scheme of della Porta and of de Caus embodied the idea of generating pressure simply by the aid of steam, whereas Hero had depended in most of his apparatus on the expansive property of air compressed by the water itself.

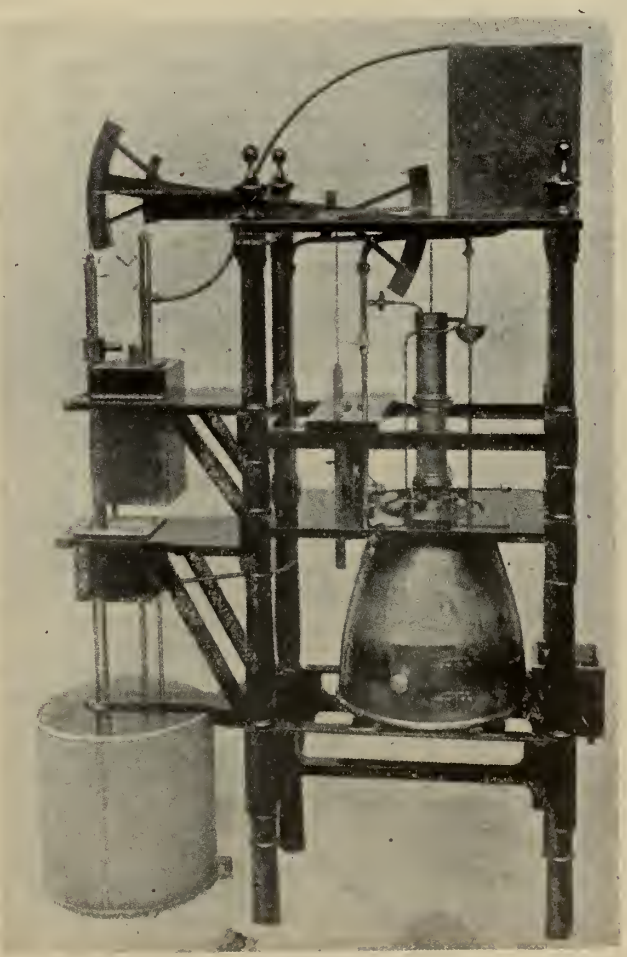

FIG. 5—A NEWCOMEN ENGINE MODEL—IT WAS ON A MODEL OF THIS TYPE THAT JAMES WATT FIRST EXPERIMENTED.

While these early mechanisms contained the germ of an idea of vast importance, the mechanisms themselves were of trivial utility. It is not even clear whether their projectors had an idea of the properties of the condensation of vapor, upon which the making of the practical steam engine so largely depends. This idea was probably first grasped about half a century later by an Englishman, Edward Somerset, the celebrated Marquis of Worcester, who, in 1663, described in his "Century of Inventions" an apparatus for raising water by the expansive force of steam. His own account of his invention is as follows:

"An admirable and most forcible way to drive up water by fire; not by drawing or sucking it upwards, for that must be as the philosopher calleth it, intra sphaeram activitatis, which is but at such a distance. But this way hath no bounder, if the vessel be strong enough; for I have taken a piece of whole cannon, whereof the end was burst, and filled it three-quarters full of water, stopping and screwing up the broken end, as also the touch-hole; and making a constant fire under it, within twenty-four hours it burst and made a great crack; so that having a way to make my vessels so that they are strengthened by the force within them, and the one to fill after the other, I have seen the water run like a constant stream, forty feet high; one vessel of water, rarefied by fire, driveth up forty of cold water; and the man that tends the work is but to turn two cocks, that one vessel of water being consumed, another begins to force and refill with cold water, and so successively; the fire being tended and kept constant, which the self-same person may likewise abundantly perform in the interim, between the necessity of turning the said cocks."

It is unfortunate that the Marquis did not give a more elaborate description of this remarkable contrivance. The fact that he treats it so casually is sufficient evidence that he had no conception of the possibili-

ties of the mechanism, but, on the other hand, his description suffices to prove that he had gained a clear notion of, and had experimentally demonstrated the tremendous power of expansion that resides in steam. No example of his steam pump has been preserved, and historians of the subject have been left in doubt as to some details of its construction, and in particular as to whether it utilized the principle of a vacuum created through condensation of the steam.

Thomas Savery's Steam Pump

This principle was clearly grasped, however, by another Englishman, Thomas Savery, a Cornish mine captain, who, in 1698, secured a patent for a steam engine to be applied to the raising of water, etc. A working model of this machine was produced before the Royal Society in 1699. The transactions of the society contain the following: "June 14th, 1699, Mr. Savery entertained the Royal Society with showing a small model of his engine for raising water by help of fire, which he set to work before them; the experiment succeeded according to expectation, and to their satisfaction."

The following very clear description of Savery's engine is given in the introduction to Beckmann's History of Inventions:

"This engine, which was used for some time to a considerable extent for raising water from mines, consisted of a strong iron vessel shaped like an egg, with a tube or pipe at the bottom, which descended to the place from which the water was to be drawn, and another at the top, which ascended to the place to which it was to be elevated. This oval vessel was filled with steam supplied from a boiler, by which the atmospheric air was first blown out of it. When the air was thus expelled and nothing but pure steam left in the vessel, the communication with the boiler was cut off, and cold water poured on the external surface. The steam within was thus condensed and a vacuum produced, and the water drawn up from below in the usual way by suction. The oval vessel was thus filled with water; a cock placed at the bottom of the lower pipe was then closed, and steam was introduced from the boiler into the oval vessel above the surface of the water. This steam being of high pressure, forced the water up the ascending tube, from the top of which it was discharged, and the oval vessel being thus refilled with steam, the vacuum was again produced by condensation, and the same process was repeated. By using two oval steam vessels, which would act alternately—one drawing water from below, while the other was forcing it upwards, an uninterrupted discharge of water was produced. Owing to the danger of explosion, from the high pressure of the steam which was used, and from the enormous waste of heat by unnecessary condensation, these engines soon fell into disuse."

This description makes it obvious that Savery had the clearest conception of the production of a vacuum by the condensation of steam, and of the utilization of the suction thus established (which suction, as we know, is really due to the pressure of outside air) to accomplish useful work. Savery also arranged this apparatus in duplicate, so that one vessel was filling with water while the other was forcing water to the delivery pipe. This is credited with being the first useful apparatus for raising water by the combustion of fuel. There was great waste of steam needless to say, through imparting heat to the water, but the feasibility of the all-important principle of accomplishing mechanical labor with the aid of heat was at last demonstrated.

The Piston Engine of Denis Papin

The principle of causing expanding steam to press against a piston working tightly in a cylinder seems to have originated with a Frenchman, Denis Papin, a scientific worker, who, being banished from his own country, was established as professor of mathematics at the University of Marburg. He conceived the important idea of transmitting power by means of a piston as early as 1688, and about two years later added the idea of producing a vacuum in a cylinder, by cooling the cylinder—the latter idea being, as we have just seen, the one which Savery put into effect.

It will be noted that Papin's invention antedated that of Savery; to the Frenchman, therefore, must be given the credit of hitting upon two important principles which made feasible the modern steam engine. Papin constructed a model consisting of a small cylinder in which a solid piston worked. In the cylinder beneath the piston was placed a small quantity of water, which, when the cylinder was heated, was turned into steam, the elastic force of which raised the piston. The cylinder was then cooled by removing the fire, when the steam condensed, thus creating a vacuum in the cylinder, into which the piston was forced by the pressure of the atmosphere.

Such an apparatus seems crude enough, yet it incorporates the essential principles, and required but the use of ingenuity in elaborating details of the mechanism, to make a really efficient steam engine. It would appear, however, that Papin was chiefly interested in the theoretical, rather than in the really practical side of the question, and there is no evidence of his having produced a working machine of practical power, until after such machines worked by steam had been constructed elsewhere.

The Improved Engine of Thomas Newcomen

As has happened so frequently in other fields, Englishmen were the first to make practical use of the new ideas enunciated above. In 1705 Thomas Newcomen, a blacksmith or ironmonger, and John Cawley, a plumber and glazier, patented their atmospheric engine, and five years later, Newcomen had on the market an engine which is described in the Report of the Department of Science and Arts of the South Kensington Museum, as "the first real pumping engine ever made."

The same report describes the engine as "a vertical steam cylinder provided with a piston connected at one end of the beam, having a pivot or bearing in the middle of its length, and at the other end of the beam pump rods for working the pump. The cylinder was surrounded by a second cylinder or jacket, open at the top, and cold water could be supplied to this outer cylinder at pleasure. The single or working cylinder could be supplied with steam when desired from a boiler below it. There was a drain pipe from the bottom of the working cylinder, and one from the outer cylinder. For the working of the engine, steam was admitted to the working cylinder, so as to fill it and expel all the air, the piston then being at the top, owing to the weight of the pump rods being sufficient to lift it; then the steam was shut off and the drain cocks closed and cold water admitted to the outer cylinder, so that the steam in the working cylinder condensed, and, leaving a partial vacuum of pressure of the atmosphere, forced the piston down and drew up the pump rods, thus making a stroke of the pump. Then the water was drawn off from the outer cylinder and steam admitted to the working cylinder before allowing the piston to return to the top of its stroke, ready for the next down stroke."

From this point onward developments in the use of steam engines spread rapidly, and this engine of Newcomen's, illustrated in figure 5, was used rather widely in its time, especially after they had been supplied with automatic valve gear. We are told that in the neighborhood of Newcastle alone there were, in 1767, fifty-seven at work, ranging in size from twenty-eight inch to seventy-five inch cylinder diameter, and giving collectively about twelve hundred horsepower.

It is interesting to note that one of these engines of Newcomen's preserved at Wednesbury, near Birmingham, was put to a trial under steam but a few weeks ago in preparation for the centenary celebration at Birmingham. The engine was in continuous use for more than half a century. Designed for thirteen strokes to the minute, the ancient piece of machinery maintained sixteen strokes to the minute at the trial.

Elevator Hazards and the Public

The Elevator Has Dangerous Possibilities in Spite of the Excellent Service That the Majority of Them Give Day After Day. The Following Paper Read Before the Annual Congress of the National Safety Council Gives a Resume of Elevator Hazards

By DANA WEBSTER, Aetna Life Insurance Co., Indianapolis

BEFORE making any remarks on the safety of elevators, it might be interesting to cover, briefly, the gradual development in the manufacture of mechanical lifting devices.

Mechanical Lifting Devices

Lifting devices were undoubtedly used by Julius Caesar as far back as 256 B.C., as history mentions their lifting animals from the dens to the arena in the Coliseum of Rome. About the middle of the Nineteenth Century, platforms or cable-hoisted elevators were first installed in New York and Boston, but were not provided with any kind of safety devices, and, strange to say, you can find a few elevators without safety devices at the present time.

A few years later elevators were equipped with safety devices of such type that it was necessary for the hoist cable to break before the safety could actuate. There are a great many of this type of safety in use to-day, but with the introduction of high-speed elevators, which were required to meet the demands of the public, quite naturally it necessitated much better type of safety apparatus and a multiplicity of cables.

Accidents could, and did occur, from over-speeding elevators, caused by disarrangements of the controlling apparatus, and it became necessary to provide safety devices that would actuate should the elevator speed increase beyond a predetermined number of feet per minute.

The most essential elements of safety are the prevention of excessive speed from any cause, the over-running of the limits of travel at top and bottom, safe protection at the landing entrances to the elevator, and a regular examination of the cables and all parts of the elevator equipments.

Car Safety Device

The early type of the safety device was designed to stop the car instantaneously. They served the purpose satisfactorily for slow speed, but were not adequate for the higher speed of 400 to 700 feet per minute. It, therefore, became necessary to provide a safety device that would stop the car with an easy and gradual stop. This is accomplished by the friction clamp safety, which is actuated by a safety speed governor, usually set to trip at 40 per cent. above regular speed. This governor will act should the hoist cable break, allowing the car to drop, or should the car over-speed from some defect in the machinery after the governor trips and the car has dropped far enough to take up the clearance of the safety jaws. The jaws are forced hard against the guide rail (like a vice), and the car will continue to slide until the friction is enough to stop the car entirely. The distance the car will slide after the safety takes hold, depends upon the load; but the farther the car slides the tighter the safety grips the rail. Usually, a car will drop about six feet after the governor trips and clamps the governor cable.

Over-running of Limit Stop

The machine of all power-operated elevators should be equipped with automatic limit stops; that is, a device that will stop the elevator at the top and bottom limit of travel, regardless of the operator.

On Drum machines, the Automatic Limit Stop should be built with and made a part of the machine.

On Hydraulic elevators, the Automatic Limit Stop should consist of a Cut-off Valve, either in the to-and-from pipe, or in both the supply and discharge pipe.

On Traction type of elevators, the Automatic Limit Stops must be located in the hoistway, and the power cut off by the travel of the car. As there is more or less slippage of the hoist cables on the drive sheave, a machine automatic would not be dependable. In addition to automatic limit stops on electric elevators, there are hoistway limit switches located so that, should the car travel a certain distance by the automatic limit stop, the car would open a switch, thus cutting off the power and stopping the machine.

Safe Protection at Landings

The early types of passenger elevators —and, in fact, most elevators up to the present time—are provided with landing doors equipped with a catch located on the inside, so that the door can only be opened by the operator. The operator, however, in order to make speed—and the public is partly to blame for this—starts the elevator before the door is closed, and quite often the door would not fully close and latch, thus providing a very dangerous condition. Many persons have opened the door when finding it ajar, and, looking in the hoistway, have either fallen or have been knocked down the hoistway by the car and severely injured or killed. I might say, right here, that statistics show that 85 to 90 per cent. of all elevator accidents occur at the landing doors. Therefore, it became necessary to provide the landing doors with a locking device that would prevent the doors from being opened, unless the car was at the landing; also to prevent the car from being removed away from the landing until the landing doors were closed, This is termed the Interlocking Device, or Interlocks for Landing Doors. While I believe all landing doors of passenger elevators and gates for freight elevators should be equipped with interlocks, I am sorry to say that, at the present time, only a small percentage of elevators are equipped with this device, although they are becoming more and more in general use.

Cables

The Cables are the most essential parts of the elevator equipment, and their number and size should be equal to the load with a good factor of safety. The sheave should be of ample size, and placed in alignment, to prevent chaffing of the cables on the sides.

Great credit must be given to the manufacturers for the high state of perfection these devices have brought. This fact must be admitted when considering the few accidents on elevators, compared to the large number of passengers carried. Statistics show that 10,000,000 passengers are carried in the Borough of Manhattan daily, and it is said that this number exceeds the number of passengers that ride on all the surface, elevated, and subway cars; in other words—more people ride vertically than horizontally.

A great many elevator accidents are not due to faulty design in construction, machinery, or safety device, but to the carelessness of the injured party. It, therefore, becomes necessary for the City or State to enact Ordinances and Laws regulating the construction of elevators, and enforcing their equipment with effective safety devices, in the interest of accident prevention; that is to say—to prevent a person from being injured by his own carelessness, and also by the carelessness of the operator.

Elevator Inspection

Are the Safety Devices Kept in Proper Condition? is one important question. The only way this can be accomplished is by having the elevator regularly inspected by a competent elevator inspector, who should inspect all the different safety devices, machinery, cables, etc., in fact, everything pertaining to the elevator. The landing doors should be tried to determine whether they can be opened from the outside. The car safety device should be tested to be sure that it would actuate.

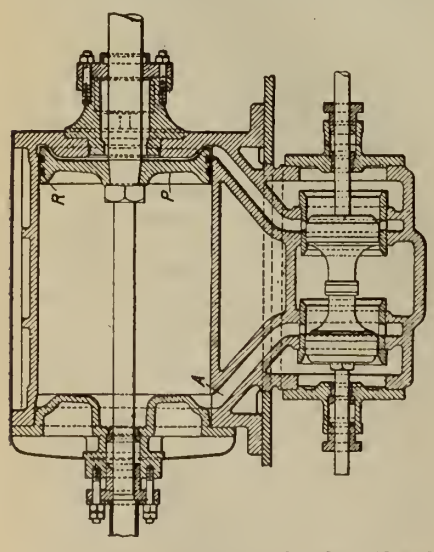
and hold the car from falling, should the cable break. The automatic limit stops should be tested so as to be sure the car will not over-run and strike the overhead beams or bumpers. The slack cable device should be tested to be positive the power would be cut off should the cables slacken. The brake should be examined to be sure there is no slippage. The cables should be examined very carefully for defects, as there is no part of an elevator that requires the exercise of more good judgment than the examination of the cables. It is just as essential that the safety devices, and all parts of the elevator, be kept in good working order, as it is that they should be installed in the first place. After an inspection has been made, the owner should proceed immediately to install safeguards and remedy any defects reported.

The elevator should be oiled and greased regularly by the engineer, and looked over carefully for any defects, and not wait for an inspector to make a thorough inspection, and oftentimes the engineer will discover some little defect which, if fixed immediately, may avoid a serious accident.

There is another feature that I wish to mention before closing; that is, the elimination of mirrors, in fact all glass, from the passenger cars (except the electric light bulbs), not only because of the fact that they are liable to cause injury to passengers by getting broken, but also because of their attraction, which results in passengers failing to notify the operator promptly as to their destination. This necessitates a stop between floors, and a trip back to let them off. They also have a tendency to retard the loading and unloading of the cars.

UNIFLOW LOCOMOTIVES

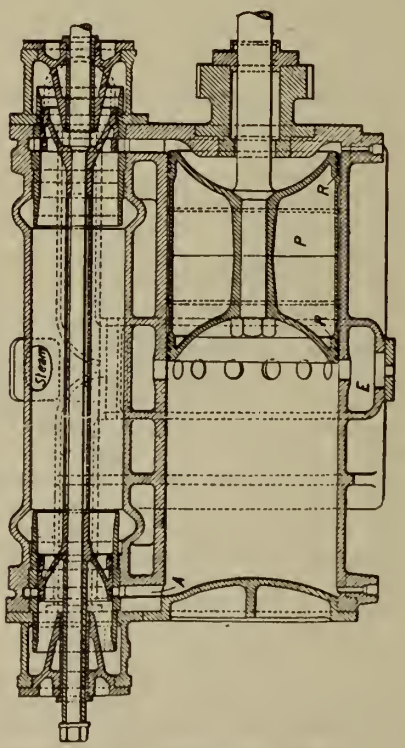
The Uniflow type of engine cylinder has been applied with considerable success in England to locomotive design.



SECTIONAL DRAWING OF ORDINARY CYLINDER.

ENGLISH UNIFLOW LOCOMOTIVE

The accompanying illustrations show the design developed by the North-Eastern Railway at the Darlington works. Three cylinders are installed, each of them 16½ in. dia. by 26 in. stroke. The design of these and their difference in appearance from the ordinary piston valve cylinder may be seen in the line drawing.



SECTIONAL DRAWING OF UNIFLOW CYLINDER.

The "Uniflow" principle differs from that of an ordinary cylinder in that the steam entering at one port does not have to return to the same point, but escapes through an exhaust port provided in the middle of the cylinder barrel. The steam, therefore, has only a forward and no backward movement; hence the term "Uniflow." Owing to the fact that the exhaust is in the middle, it is necessary to increase the length of the cylinder to about double what it would otherwise be, in order to allow the steam which enters through the port at one end of the cylinder to press forward the piston for the same length of time or distance before exhaust, as is done in the case of the ordinary engine. The piston in a "Uniflow" cylinder is called upon to govern the exhaust instead of, as in the usual type, leaving that function to the slide or piston valve. The piston is a hollow casting, with spring rings at each end, which prevent any steam passing through to its other side. It is claimed that this piston, being hollow and full of air, protects the live steam of the piston from the disadvantageous effects which the ordinary narrow piston possesses, due to its being a single solid surface, one side or the other of which is always wet from exhaust steam.

We are indebted to the North-Eastern Railway Magazine for the information contained in this article.

THE ALIGNMENT OF SHAFTS

The first indication of a shaft being imperfectly supported in its bearings is excessive end play, with the flywheel running out of truth. This is often caused by the springing of the crankshaft for want of support, the resultant effect being extension and contraction of the shaft endwise. This effect, it seems, can very well be noted without dismantling an engine; in fact, it can be done with the whole of the reciprocating parts in position. The author of the paper suggests that if delicate and careful measurements are taken between the crank webs when the crank pin is on top and bottom centres a difference of but one or two-thousandths of an inch will denote alignment inaccuracy. If an inner bearing of an engine is low the crank webs will close in slightly when the pin is on the bottom centre, and open out when the crank pin is placed on the top centre. If, however, it is an outboard bearing that is low, the reverse will be the case. Generally speaking, the amount of lack of support, or misalignment of a bearing is approximately the difference between the readings when the crank pin is at the top and bottom centre respectively. The instrument used for the measurement tests is an inside micrometer having telescopic rods. We think, however, that a dial test indicator would be more suitable.

Methods of Setting Piston Valves

The Piston Valve Has Many Advantages Over the Common "D" Slide Valve, Although Its Setting is Sometimes a More Difficult Operation. This Paper Gives Some Useful Information

By J. W: A. DRUMMOND, Drumheller, Alberta

NEARLY all vertical engines, and many types of horizontal engines, are fitted with piston valves, in the place of the common D slide-valve, to control the distribution of steam to the cylinder or cylinders.

This type of valve is particularly desirable in vertical engines, as it is possible by making the upper portion of the valve larger than the lower portion, to balance the weight of the valve and its valve-rod and thus reduce the power required to move the valve.

While the piston valve is similar in its action to a D slide-valve, its setting is not always a simple operation, as it is often placed in a cylindrical valve chest, which is covered with a valve chest cover. There being no cover plate at the side as in the case of a D slide-valve, it is necessary to use some other means of ascertaining when the valve is correctly set, and it is the purpose of this article to describe a very simple way to accomplish the desired result, accurately and quickly once the necessary equipment has been made.

I will first explain a few types of valves:—The valves are made both with and without piston rings, depending on the size and grade of the engine, the cheaper grades and smaller sizes being without piston rings. When the valve has no piston rings, the cylinder ports are plain, opening into the cylinder, as in the case of a D slide-valve, except that the openings are circular to conform with the shape of the valve chest. When the valve has piston rings, the ports have to be bridged, to prevent the possibility of the valve catching the ports. See Fig. 1 and Fig. 2.

The bridging consists of bars of metal cast integral with the cylinder casting, thus bridging the ports with narrow strips of metal, the passage between the bars being in effect a series of small ports, the sum of the area of which is that which would be required if the port were plain, when the valve chest is bored out, the portion that is bridged is also bored to the same size as the rest of the valve chest, thus leaving the port openings with a support which keeps the rings closed, and prevents them from catching in the openings (port).

There are two classes of valves, Direct and Indirect.

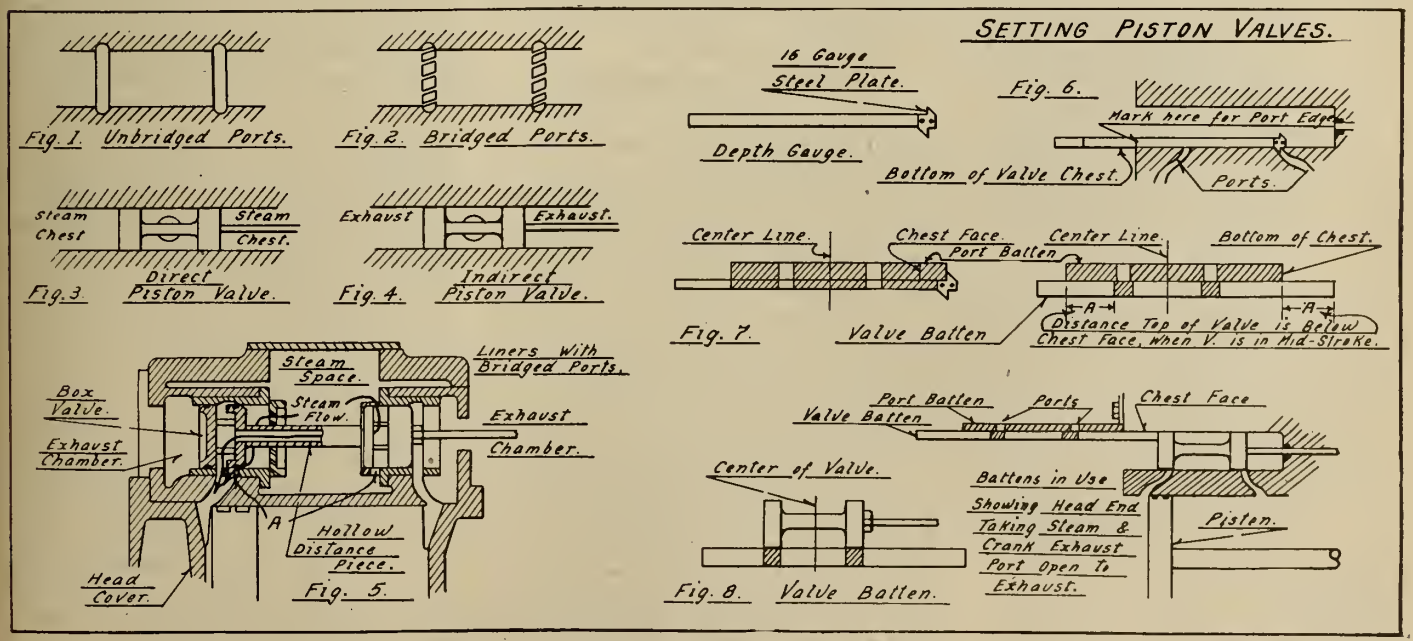
In the direct type the steam is admitted over the ends of the valves and is exhausted at the centre, in this type the lead can usually be measured at the head end, but not at the other end. See Fig. 3 and Fig. 4.

Then we have what is known as the indirect valve in which the steam is admitted to the central portion of the valve and the exhaust goes out over the ends, in this type it is not possible to measure the lead unless there is a cover plate at this side.

A third type of valve is known as the box type. It is also an indirect valve, in this valve, the ends are solid, the remaining portion of which is hollow. The two ends being held togther by a hollow distance piece, which bridges between the ends of it, and the solid ends.

When the box type of valve is used, the valve chest has a liner to each port, this liner has two ports in it, both of which are bridged, the reason there are two ports for each end of the cylinder is, the box type of valve is a double ported one, the action of which will now be explained. As will be seen in the sketch, the valve is just open the amount due to the lead, and steam is going to be admitted to the head end of the cylinder. It will be remembered that this valve is an indirect one, so the steam is admitted to the central portion of the valve chest, that being the case, the steam will be entering the cylinder through the opening at A, but on looking at the other end of the valve, it will be noticed that the hollow portion of the valve is also open to steam, so that some steam must also be passing through the valve to the other end and into the cylinder port, which is shown to be fully open to steam, so it will be plainly seen, that this valve is double ported, as the steam is admitted at two distinct ports, and in setting the valves, the lead has to be measured at the two points A, which would make this type of valve, a very difficult one to set correctly, unless the lead could be measured.

The crank end exhaust port is almost fully open, and the exhaust steam passes out over the end of the valve, to the spaces marked E, which in this case of a simple engine, is connected to a Y piece, or led through passages to the exhaust pipe, in the case of a compound engine, it may go to the receiver, or direct to the low pressure-cylinder, the same valve controlling the steam dis-



SETTING PISTON VALVES ON A STEAM ENGINE.

tribution in the L. P. by the addition of extra ports in the valve. See Fig. 5.

When an indirect type of valve is used, the eccentric has to be set behind the crank, and the angle of advance is 90 degrees, less the angle of advance, unless a reversing rocker is used, when the eccentric is set at 90 degrees, plus the angle of advance ahead of the crank, this rule is applicable no matter in which direction it is desired to run the engine.

In some types of engines, it is impossible to measure the lead directly, so that other means have to be resorted to, to set the valve, as both lead openings cannot be seen, when such is the case, one of the easiest and most accurate methods, is to proceed as follows:—

The piston valve should be removed from its valve chest, and a rod made as follows: for measuring the valve openings, a piece of flat steel say about 16 gauge, is marked out in this manner, first scribe a line across the centre lengthways, and then on the centre line on the other axis mark off the width of the stick to which it is to be attached, say ¾-in. wide, now on the horizontal centre line, mark off the width of the stick, a distance of ½-in., make the width of the plate about one and one-half inches, and join the marks on the centre lines, to the corners of the plates, with a diagonal line, and file the plate to shape, then drill two holes in it to secure it to the stick, which should be about ¾-in. wide, and about ½--in. thick, and long enough to reach the bottom of the valve chest, and have about 6 in. to spare, having made this, now secure two pieces of batten, say one and one-half inches wide, by ¾ inch thick, and about the same length as the depth gauge.

See Fig. 6.

Now with the depth gauge, measure the distance to the lower edge of the steam port in the valve chest, (see sketch) and make a mark, corresponding with the face of the valve chest face, then move the gauge up to measure the position of the upper edge of the same port, and again make a mark on the gauge corresponding with the valve chest-face, proceed in this manner, till you have the ports all complete on the gauge, then find the depth of the valve chest from the chest-face, and mark the depth gauge again.

Now lay the depth gauge along side one of the battens, which should have a square end, the line corresponding with the bottom of the valve chest, is taken to be the squared off end of the batten, then the lower port is marked off, then the upper, the solid spaces between the ports being cross-hatched, and then the lines corresponding to the steam chest face, is laid off, thus completing the valve port batten. The centre line between the ports must be marked on this batten.

See Fig. 7.

Then take the piston valve and lay it on the other batten, and mark off the position of the bridges, or valve faces, and also the centre line of the valve, and the position of the end of the valve, now lay two battens side by side, with the valve centre lines corresponding, and mark off valve chest face on valve batten, this distance is the distance the top of the valve is below the valve chest face, when the valve is in the centre of its travel, on the other end of the valve batten, the line corresponding to the bottom of the valve chest, must be marked on, and from this line a distance equal to the distance the top of the valve is below the valve chest cover, when in midposition, is added, and a line drawn with a square across the batten, the remainder, is then cut off at this line, we now have our sticks complete as below, (see sketch), Fig. 8.

Now make a piece of plate bent to a right angle, with one leg long enough to catch one of the valve chest bolts, and allow the angle piece to stand over the valve chest opening, drill it to fit the valve chest studs on the long leg, and three holes to fasten port opening stick to the angle piece, having done so, replace valve in chest, bolt on the port stick to the valve chest face, now get some one to rotate the engine to crank dead centre, lay valve stick against port stick and position of valve can be seen with reference to the ports, turn engine over to the other dead centre, and again observe position of valve with reference to the ports, it can now be seen, if the valve is correctly set, and if not, which way the valve has to be moved to place it in the correct position, and by having some one to turn the engine over, the action of the valve can be followed throughout.

Having once made a set of sticks, for an engine, of which you have charge, they should be preserved, as they form a very simple and quick method of replacing an eccentric in its proper place, should it chance to slip, or should it be necessary to check up the valve setting at any time.

PRIMING REMEDIES

A general indication leading one to think boiler priming is taking place is the violent agitation of the water in the gauge glass, together with its muddy and discolored appearance. Sometimes this level will record as much as two inches of difference within the space of a few seconds; sometimes disappearing below or above the glass altogether. If it is thought that fluctuation of steam demands is giving rise to the trouble close down the boiler stop valve a little.

The anti-priming pipe, usually found in Lancashire or Galloway type boilers, is a slotted pipe fixed inside the boiler towards the top, cast in sections and bolted together. This pipe should be at least three-quarters the length of the boiler, and the area of the slots at least equal to the bore of the steam valve. Whenever the boiler is opened up for cleaning or repairs, these slots should be examined for corrosion and reduction of orifice area, as priming trouble may be due to this cause. One peculiar feature of priming is that the trouble may be apparent in a more or less greater degree with the type of labor employed in firing, thus proving that the manner in which the boiler is fired is an important factor in this respect. The thinnest film of grease clinging to the water within the boiler will sometimes give rise to priming, hence care should be taken to eliminate this from the feed-water. Boiler compositions introduced for the purpose of reducing scale must be used sparingly and in small quantities at a time. A day's supply should not be injected within a few minutes by means of the boiler pump or injector; instead, it should be spread over a whole day's supply of feed-water. Priming due to a high-water value can be remedied by lowering the water line, but in this expert advice should be taken in order that the danger limit is not reached.

INTERNAL COMBUSTION ENGINE IMPROVEMENTS

Important improvements continue to be made by British engineers in the Diesel oil engines which are being so largely adopted for marine purposes and for the generation of electricity on land. One recent innovation is intended to enable tar oil to be successfully used as the fuel. A pilot jet of paraffin is provided to form a flame for the following jet of tar oil, thus overcoming the difficulties of ignition. Another novelty which is of special interest to central station engineers is a device for automatically controlling the pressure of the air supply to suit the varying loads met with in the supply of electricity. On one and the same gauge is a pointer registering the air blast pressure and another controlled by the current passing through the generator. The second pointer is arranged to indicate the correct air pressure according to the load on the generator, and everything is in order when the two pointers are together, in which position they close an electrical circuit controlling the compressor throttle. When the pointers are apart, the throttle opens and increases he air supply until the pointers come together. Greatly improved combustion is secured by this ingenious device. Another British firm has introduced an emergency governor which stops the engine completely in case of an excessive rise in speed—an emergency which is beyond the ordinary governor. This apparatus, works by by-passing the fuel into the atmosphere. Another emergency device stops the engine whenever the water circulation fails, the apparatus being operated by a diaphragm, which flattens when the water pressure upon it is withdrawn. All the British makers concerned in this field are standardizing their designs in order to provide the advantages of mass production.

Water Hammer Action

The Following Article, Reprinted from "The Locomotive," Gives Some Interesting Facts Relative to This Power Plant Trouble. The Theory of This Obscure Action is Well Explained

"WATER-HAMMER action" is the action which occurs in a steam boiler or in steam piping, when a mass of water is driven with considerable velocity against a solid body, or against another mass of water, in such a way as to have its motion suddenly checked or destroyed. Under these circumstances a severe momentary pressure is generated in the region where the collision occurs, just as happens when we bring a heavy sledge hammer down forcibly upon an anvil. If the moving water strikes directly against the boiler shell, the pressure is exerted directly against the shell; while if the moving mass is stopped by colliding with another mass of water, the pressure arises in the midst of the fluid, where the collision occurs. In the latter case, however, a pressure-wave is generated in the water, and this travels forward until it presently comes to bear against the shell of the boiler. In either case, therefore, the shell will be subjected to a shock, as the result of the sudden stoppage of the moving water; and under suitable conditions this shock may be very heavy indeed—quite sufficient, in fact, to rend the boiler.

Conditions for the Development of Water-Hammer Action

It is plain, from what has been said, that the immediate conditions for the development of water-hammer action are two in number. (1) Some portion of the water must be caused to move with a considerable speed, and (2) this moving mass must strike against the boiler, or against another mass of water, in such a way that its own speed is suddenly checked or destroyed. The pressure which is generated is only momentary, but it may be of great intensity during the instant it lasts.

The violent commotion which precedes and leads to the water-hammer effect cannot arise unless there are sensible differences of pressure or of temperature, within the boiler. There can be no water-hammer action, for example, in a boiler whose contents are everywhere at the same temperature and pressure.

In practice we find that the action develops in undrained steam pipes when steam is turned into them, and in boilers which are being cut in with a steam main which is already in communication with other boilers; but in order to realize it, the conditions referred to above must be fulfilled. That is, the water and steam must be at different pressures, or at different temperatures.

When a boiler is cut into a steam main, it will be the difference in pressure which determines the action, provided the pressure in the boiler exceeds that in the main; for when we open the stop-valve under these circumstances, the water in the boiler will tend to "lift," and considerable masses of it may be thrown against the shell, with a resultant shock which may be sufficient to produce rupture.

Conversely, if the pressure in the boiler is less than that in the main, the action will be primarily due to the difference in temperature between the steam in the pipe and the water in the boiler. (This will appear later.)

The case in which the pressure in the boiler is greater than that in the pipe, and the action consists in the lifting of the water, is undoubtedly the better understood of the two, and we shall therefore dwell, in this article, upon the second case, in which the pressure in the boiler is less than that in the main. This

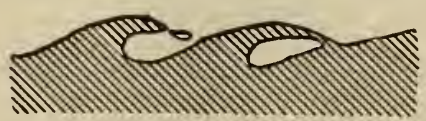


FIG. 1—FORMATION OF A BUBBLE.

second case appears to be widely misunderstood by engineers in general and yet it is the one which is most likely to arise in practice; for in firing up a boiler which has been out of service for a time, the attendant is far more likely to cut it in as soon as the pressure approaches that in the main, than he is to wait until it is higher. In fact, it is a more or less common (though highly dangerous) practice, to cut in the boiler as soon as the pressure comes up to within (say) ten or fifteen pounds of that prevailing in the pipe line at the time.

Our attention has been called quite recently to a plant in the South, where the practice was, for a time, to fill up a boiler with comparatively cold water, and then to open its stop-valve at once, so that the steam in the main would assist in bringing the water up to the operating temperature. It seems incredible that this can be true, and the boiler still remain upon earth; but from the representations which have been made to us we are forced to believe it. At all events the practice has been discontinued in that particular plant, on account of certain emphatic counsel given by our inspector. The superintendent of the plant admitted, by the way, that the boiler occasionally "jumped some" while it was being warmed up. Why it didn't jump a couple of miles is a mystery which we cannot solve.

The Two Points of View

We may look at the water-hammer problem from two different points of view. Thus we may ask ourselves (1) what pressure may be produced within a boiler by water-hammer action, or we may ask (2) what is the maximum mechanical work which can be performed, under given circumstances?

The first of these questions cannot be answered with any approach to precision, partly because we never know, in any given case, just how the water in the boiler is thrown about, and partly because the entire theory of impact is still in an imperfect state, as we have already explained at some length, in the issue of "The Locomotive" for July, 1909. The second question can be definitely answered, however, since, in solving it, we do not need to know the exact way in which the disturbance of the water takes place.

We shall take up these two questions in order.

Nature of the Disturbance in the Boiler

In dealing with the momentary pressure which water-hammer can produce in a boiler, we have, first, to get over a line of reasoning very similar to that given in "The Locomotive" for July, 1909; so that we can here treat the matter more briefly than might otherwise be permissible, referring the reader, for a further elucidation of the principles, involved, to the articles in the issue cited.

The steam which is discharged into the boiler from the main disturbs the surface of the water, and generates waves; and the moment one of these waves breaks, so as to form a sort of bubble enclosing some of the steam, the water-hammer action begins. (See Fig. 1.) For, by hypothesis, the water is somewhat cooler than the steam (on account of the original pressure in the boiler being lower than that in the main), and it follows that the steam enclosed within the bubble will condense, leaving a partially vacuous space there. The pressure acting upon the surface of the water will then close the bubble up almost instantly, the water which forms its upper wall being brought down against that which forms the bottom of it, with great speed and corresponding violence. The hammering action thus initiated will increase the disturbance in the water, and larger bubbles will be formed in the same way, with the production of increasingly violent shocks when they collapse.

A more concrete idea may be had of the action by considering the familiar operation of blowing steam into cold water from a small pipe. A bubble of

steam forms momentarily, and is immediately condensed by the cooler water, the sides of the bubble coming together with a resounding crack. In the boiler the case is similar, but the experiment is there performed on a terrible scale, with steam furnished by a battery of boilers, through a six-inch pipe (perhaps) instead of a quarter-inch one, and with the bubbles, quite likely as big as water pails, collapsing under a pressure of 100 pounds or so, per square inch, instead of under simple atmospheric pressure.

Ideal Case of a Cylindrical Plug of Water

In order to estimate the magnitude of the momentary pressure which is produced in the water by these sudden shocks, we proceed as follows:

Consider first (as in our previous article of July, 1909, already cited), the case of a cylindrical plug of water, moving along the interior of a smooth cylindrical tube which it just fills. (See Fig. 2.) Underneath the plug there is a space which is filled, at the outset, with steam fresh from the main steam pipe, and having therefore a temperature higher than that of the water in the boiler. Now let us suppose that the imaginary tube in which the plug travels is surrounded by water at the temperature which prevails in the boiler, and that the walls of the tube are not real walls, of metal, but that they are imaginary, permitting the free passage of heat, while not allowing the water composing the plug to flow out sidewise.

Under these circumstances the steam under the plug, being surrounded by water cooler than itself, will partially condense. Its pressure will promptly fall, in fact, to the pressure corresponding to the temperature of the water.

If we represent the pressure in the steam main by p_1, and the reduced pressure below the plug by p_2, and if we also assume that the sectional area of the plug is one square inch, we see that (as indicated in Fig. 2) the plug is subject to a downwardly-directed force equal to p_1, and an upwardly-directed force equal to p_2. Since p_1 is greater than p_2, the resultant force acting on the plug is downward, and equal to $p_1 - p_2$. In forcing the plug downward through a distance of V inches, so as to cause the space under it to disappear, the work done by the steam is therefore $(p_1 - p_2)$ V inch-pounds.

As soon as the plug strikes the water below it, a pressure is produced at the surface where the two come together, accompanied by a local compression of the water along that surface, in the vertical direction. This pressure at the surface of contact acts downward on the free substratum of water, and upward on the water-plug. The motion of the plug is arrested at this point, but the rear (or upper) part of the plug will continue to press forward, for a moment, after the front part has become stationary. So far as the pressure within the water is concerned, the effect will be as though there were a wave of compression transmitted through the water, traveling with the same velocity as sound (since sound is only a succession of compression waves). As soon as the wave of compression has passed back through the plug and reached its rear (or upper) surface, this rear surface will also become stationary, and for an instant the entire plug will be motionless and in a state of uniform compression. The compressive stress to which it is subjected at this instant, by reason of its own sudden loss of momentum is, in fact, the "water-hammer pressure" which we are seeking to determine.

The water below the plug will be compressed, in just the same way as is the water of the plug itself; and since the compression wave will have the same velocity, downward through the free water, as it has backward through the

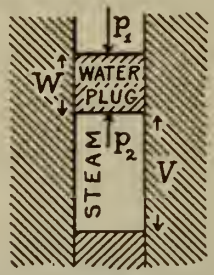

FIG. 2—THE CYLINDRICAL PLUG OF WATER

plug itself, it follows that at the moment when the pressure-wave reaches the back end of the plug (the length of which we will call W inches), it will also have penetrated the water below the plug to the same distance. Hence, at the instant the plug comes to rest, there will be a total volume of water under compression, equal to 2W cubic inches (the sectional area of the plug being one square inch); half of this being the volume of the plug itself, and the other half being the volume of that part of the free water which is also at the same time under an equal compression.

If we think of this volume 2W, as being under a momentary uniform compression equal to P lbs. per square inch, we may deduce the pressure, P, by the following process: Let C, be what is termed the "modulus of compressibility" of water. That is, C is the pressure, per square inch, which would suffice to compress the water to nothing, if its diminution of volume, at indefinitely high pressures, should follow the same law which holds for pressures which are moderate. (Of course there is no pressure which actually would compress the water to a zero volume; but the "modulus of compressibility," as defined above, is an exceedingly convenient thing to use, in practical computations.) Also, let x be the amount by which the volume 2W of the compressed water is reduced by the actual (though as yet unknown) pressure P. We then have the proportion

$$P : C :: x : 2W$$

And solving this for x we find

$$x = \frac{2PW}{C}$$

The work done in compressing a liquid is very nearly independent of the way in which the compression is performed. (We mention this, because the fact is quite otherwise with a gas or vapor.) Hence the potential energy stored up in the compressed water will be the same (or sensibly the same) as it would be if we effected the compression slowly and uniformly, beginning with the pressure at zero, and gradually increasing it up to P. Now in this case the average pressure applied would be ½P; and multiplying this by x (the height by which the volume 2W has been reduced), we find that the total work done would be ½Px. And if we replace x by its value as just found, above, we see, finally, that the potential energy stored in the 2W cubic inches of water under compression is

$$\frac{P^2 W}{C}$$

Now since energy cannot be created nor destroyed, this must be equal to the work done by the steam in pushing the plug to the end of its cylindrical passage; and hence we have the equation

$$(p_1 - p_2)\ V = \frac{P^2 W}{C}$$

which, upon being solved for P, gives

$$P = \sqrt{\frac{(p_1 - p_2)\ C\ V}{W}}$$

This, it is to be remembered, is the expression for the pressure which may be produced in the ideal case, in which a plug of water is driven along a cylindrical channel so as to come suddenly and violently against another mass of water of equal cross section, and extending indefinitely in the direction of the length of the channel.

Application to the Actual Case

In order to see how the foregoing formula for P applies in the actual case which arises in practice, let us consider a bubble of rectangular shape, such as is indicated in Fig. 3. This consists, as will be seen, of a sort of slab of water, of thickness W, raised to a distance V. Let us imagine the upper slab, the space below it, and the water which lies below the space, to be divided into imaginary cylindrical tubes, as suggested by the dotted lines. If now, the top wall, or slab, comes down uniformly in all its parts when the bubble collapses, the water in each of these imaginary cylindrical tubes will act just as we have supposed the plug to act, in the ideal tube described above. There will be no sidewise flow of the water, or none of any account, provided the rectangular bubble is big enough in its horizontal

dimensions. Hence the formula will be as applicable to this case, as it is to the case of the single plug in its cylindrical tube.

Finally, if the bubble, instead of being rectangular, is more or less oval or ellipsoidal, as in Fig. 4, the pressure actually developed will agree with the calculated pressure to an order of approximation corresponding to the (unknown) degree in which the conditions in the actual case conform with those which were assumed to exist, in deriving the formula.

After the pressure which is due to the impact has been generated, it is transmitted through the water to the boiler shell. In this transmission it will be somewhat lessened in intensity, and it will be propagated mainly in the direction in which the top slab of the bubble collapses.

We have supposed, for the sake of simplicity, that the bubble collapses vertically; but since the water in the boiler is thrown about in an utterly indescribable manner, the actual collapse may take place horizontally or obliquely, and hence the maximum pressure may be exerted upon the boiler shell sidewise, or in any other direction.

The formula may be expressed in words as follows: First find the difference $(p_1 - p_2)$ between the pressure in the steam main and that in the boiler before opening the valve, and multiply this by the modulus of compressibility of water (C), which may be taken as equal to 300,000 lbs. per square inch. Then multiply again by the depth (V), in inches, of the steam inside of the bubble, measuring this depth in the direction in which collapse takes place. Finally, divide the product so obtained by the thickness of the upper layer (W) of the bubble, in inches, and take the square root of the quotient. The result will be the momentary pressure produced in the water by the collapse of the bubble.

This rule, be it understood, cannot be used to determine anything but the general order of magnitude of the pressures produced by water-hammer. No rule could do more than this, however, when applied to a problem as indefinite as the one with which we are dealing. Yet with all its limitations the rule has a considerable value, since it shows that water-hammer effects may be exceedingly serious, and that we need to guard against their production, with the greatest care.

Numerical Example

Let us now apply the formula to the calculation of the maximum possible pressure which water-hammer might produce, in a particular case. We shall suppose, for this purpose, that a boiler is being cut in with others, and that the pressure it carries is less than that prevailing in the steam main at the time. We shall assume that the pressure in the main is 95 lbs. per square inch, and that in the boiler is 88 lbs. per square inch.

In this example, as in all others of like nature, we shall have to arbitrarily assume the thickness of the bubble and of the top layer thereof. We cannot tell what these thicknesses were, but we must endeavor to choose values for them which might reasonably be expected to occur. Let us suppose that the thickness of the steam-filled portion of the bubble was 6 in., and that of the slab, or top portion, was 3 in. Then our rule works out as follows: The difference between the pressure in the steam main and that prevailing in the boiler just before opening the stop-valve was 95 — 88 = 7 lbs. per square inch. This, multiplied by 300,000, gives 300,000 × 7 = 2,100,000. Multiplying again by the thickness of the steam space of the bubble, we have 2,100,000 × 6 = 12,600,000. Then, dividing this by the thickness of the top layer of the bubble, we have 12,600,000 ÷ 3 = 4,200,000. And, finally, taking the square root of this last number, we have $\sqrt{4,200,000} = 2,049$ lbs. per square inch, which is the maximum pressure which could be developed by water-hammer action in the given boiler, under the assumed conditions. It is evident, here, that we may make very large allowances indeed for the fact that the conditions may not have been just like those presupposed, and yet we shall have a pressure quite sufficient to cause rivets, or any other part of the boiler, to snap at once—especially when we remember that the instantaneous pressure developed by the water-hammer action was in addition to the normal load of 95 lbs. per square inch, which the steam exerted upon the shell directly, as soon as the stop-valve was opened.

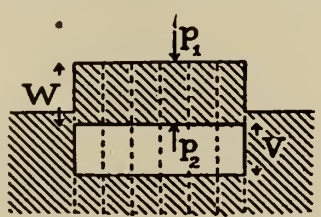

FIG. 3—RECTANGULAR BUBBLE.

Once again we may state that when a boiler is burst by water-hammer action, the pressure which is generated acts only for an instant, and its effect upon the boiler is similar to that of a sudden hydrostatic pressure. That is, it disrupts the boiler, but it does not throw the pieces about. The momentary water-hammer pressure having separated the parts of the boiler, it is the normal steam pressure within the boiler which does the rest of the work.

The Maximum Amount of Mechanical Work Which Can Be Performed

We come now to the second aspect of the water-hammer question. Namely, we have to look at the case from the following point of view, which is more general than the one from which we have approached it above. A boiler containing a mass of water at a given temperature is placed in free communication with a steam main capable of supplying a practically unlimited amount of steam at a pressure higher than that due to the temperature prevailing within the boiler. As we have here two bodies, or substances, at two different temperatures (namely, the steam in the main and the water in the boiler), the theory of heat teaches us that a certain amount of mechanical energy can be developed, as an accompaniment to the process of temperature-equalization which at once begins. The quantity of mechanical energy which can be so developed, however, is strictly limited by the laws of thermodynamics; and it is not at all difficult to find an expression from which its maximum amount can be calculated.

Let t_1 be the temperature of the steam which is admitted from the steam main —this being constant throughout the entire operation, since the steam is furnished by outside boilers, at a constant pressure and temperature. Also let t_2 be the temperature which the water in the boiler has at the outset, just as the stop-valve is opened. As soon as the steam, at the higher temperature t_1, enters the boiler, it comes in contact with the cooler water there, and begins to condense; and although the heat which it gives out in condensing may be partially converted into mechanical energy, available for throwing water in the boiler about, the major portion of it must go to the direct heating of the water, without the production of any such mechanical work. In fact, the principles of thermodynamics, upon which we have dwelt in many of the previous issues of "The Locomotive," show that when, in the equalizing process, the incoming steam gives up a small quantity of heat—a quantity so small, namely, that it does not materially alter the temperature of the water in the boiler as a whole—we may find the maximum quantity of mechanical energy which can be developed, by multiplying this small quantity of heat (expressed in foot-pounds) by the fraction

$$\frac{t_1 - t_2}{t_1 + 459.7^\circ}$$

the constant number 459.7° being the Fahrenheit temperature of the Fahrenheit zero, on the absolute scale of temperature.

If, as in the example worked out above under the other rule, we take the pressure in the main at 95 lbs. per square inch, and that in the boiler before the stop valve was opened at 88 lbs., we find, by consulting a table of the properties of steam, that the temperature (t_1) of the steam in the main was 334.4°, and the temperature (t_2) of the water in the boiler was 329.5° Fahr. Hence $t_1 - t_2 = 334.4^\circ - 329.5^\circ = 4.9^\circ$, and $t_1 + 459.7^\circ = 334.4^\circ + 459.7^\circ = 794.1^\circ$. With these values of the temperatures, the foregoing fraction becomes equal to 4.9 ÷ 794.1 = 0.00617; so that when the entering steam begins

to condense, the first foot-pound of heat which it gives up can generate 0.00617 of a foot-pound of mechanical energy, which can manifest itself by throwing the water about; but the remaining 0.099383 of the foot-pound must pass directly and quietly into the water, without appearing in the mechanical form at all.

As the water in the boiler rises in temperature, owing to the heat which it is receiving from the steam, the same sort of calculation can be made at every stage of the process. The only difference will be that the value of t_2 will increase as the water warms up, while the value of t_1 remains constant. The fraction hich expresses the proportion of the heat which can be converted into mechanical energy will grow less, therefore, as the temperatures become equalized. The average value of the expression given above for the efficiency of the conversion is

$$\frac{1}{2}\,\frac{t_1 - t_2}{t_1 + 459.7^\circ};$$

and if we multiply this last expression by the amount of heat given up by the steam, we shall have the total amount of mechanical energy which can be developed, within the boiler as a result of cutting it into the steam line, at a temperature (or pressure) below that of the steam in the main.

Now the total amount of heat which is given up by the steam is equal to that absorbed directly by the water, plus that which is converted into mechanical energy. But since considerably more than 99 per cent. of that which the steam gives up is directly absorbed by the water, we shall not commit any error of the slightest practical importance if we assume, in this particular calculation, that the two are equal. If the average specific heat of the water between t_1 and t_2 is S, then each pound of water, in becoming warmed from t_2 to t_1, will absorb S $(t - t_2)$ units of heat. To express this quantity of heat in foot-pounds, which is a more convenient way for our present purposes, we have merely to multiply it by Joule's equivalent, which we will take at 780 foot-pounds per Fahrenheit heat unit. Moreover, we may take the specific heat, S, of the water as equal to unity. Hence, the total quantity of heat absorbed by the water is 780 $(t_1 - t_2)$ foot-pounds. Assuming that this is equal to the amount given up by the steam (as explained above), we have merely to multiply it by the fraction given in the preceding paragraph, and again by the number of pounds (say w) of water in the boiler, and we have the total number of foot-pounds of mechanical energy which can be developed when the boiler is cut in with its fellows. Thus the expression in question becomes

$$\frac{390w\ (t_1 - t_2)^2}{t_1 + 459.7^\circ}$$

In words, this may be expressed as follows: Find the square of the difference in temperature between the steam in the main and the water in the boiler, multiply this by the number of pounds of water in the boiler, and multiply again by the constant number 390. Then divide the product so obtained by the temperature of the steam plus 459.7°. (Fahrenheit temperatures are to be used.) The result is the greatest possible number of foot-pounds of mechanical work which the water can do, in being thrown about as a consequence of the boiler being cut in before the pressure within it has become equal to that prevailing at the time in the steam main.

Application to a Numerical Example

By way of illustration, we shall apply this formula to the same example as before. We have already found the difference of temperature between the

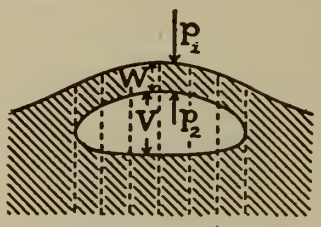

FIG. 4—OVAL BUBBLE.

water and the steam to be 4.9°. The square of this is $4.9 \times 4.9 = 24.01$. We shall throw away the small decimal, and call it 24. We next need to know the total weight of water in the boiler, and for the purposes of illustration we shall take this to be 12,000 lbs. Then proceeding with the application of the rule, we have $12{,}000 \times 24 = 288{,}000$; and $288{,}000 \times 390 = 112{,}320{,}000$. We have already found that $t_1 + 459.7^\circ = 794.1$. Hence we have $112{,}320{,}000 \div 794.1 = 141{,}440$ foot-pounds, which is the maximum quantity of mechanical energy which could be developed inside of the boiler, as a consequence of cutting it in with the others before the pressure had become equalized to within less than seven pounds per square inch.

As before, this result is merely a maximum one, but in obtaining it we do not have to make any supposition respecting the proportions of the steam bubbles which are formed. The result is exact, save that we have made certain assumptions of a merely arithmetical nature, in the interest of simplicity—assumptions which certainly do not affect our conclusion by more than a few per cent.

A mere fraction of this maximum available amount of work would suffice, without doubt, to start the rivets shearing; and, as we have several times remarked, it is the steam pressure normally within the boiler which throws the parts asunder, when once the work of disruption has been well begun. The energy developed directly by the water-hammer does not have to account for any portion of the mechanical work of the explosion, save that which is required to stress some parts up to their breaking points.

We would direct attention particularly to the fact that the quantity of mechanical energy which can be developed within the boiler, and be manifested by throwing the water about with more or less violence, varies as the square of the difference in temperature between the water and the steam. Hence if this difference were twice as great as we have assumed, the quantity of mechanical energy which could be developed, under otherwise similar conditions, would be four times that calculated above.

Can the Water-Hammer Action Be Delayed?

Water-hammer action, if the conditions for its occurrence exist, usually begins the moment the stop-valve is opened. If, however, the pressure in the main exceeds that in the boiler, and the stop-valve is opened cautiously, there appears to be no reason why the steam might not enter quietly. Part of it must condense, of course, on account of the chilling action of the water upon it; but this might conceivably occur without mechanical disturbance, the superficial layers of the water in the boiler becoming heated, so that a sort of equilibrium would be established. If nothing should occur to agitate the water, this state might persist until the entire bulk of the water became heated up to the temperature of the steam in the main; and after that no water-hammer would be possible.

The pseudo-equilibrium thus established would be highly unstable, however, and the least disturbance of the water, by bringing its deeper and cooler layers to the surface, would precipitate water-hammer action at once. It would be only under the most exceptional circumstances that delayed development such as we have suggested could occur, and yet such delay is manifestly possible.

Precautions for the Avoidance of Water-Hammer Action

In conclusion, let us emphasize the fact that it is of exceeding importance, in cutting in a boiler, to be sure that the pressure upon it is as nearly identical as possible with the pressure which is prevailing, at the time, in the steam main. Mathematically, equality can hardly ever be attained, however, partly because commercial steam gauges will seldom agree to within a pound or so. Hence when the equality of pressure is judged to be exact, the stop-valve should be opened very carefully, indeed opened just a bare crack at first, and then, as the slight outstanding difference of pressure equalizes itself, opened wider, very slowly, until it is open full. The complete operation should occupy a couple of minutes or more, and the attendant should hold himself in readiness, at every instant, to close the valve at once, if there is the slightest evidence of any unusual jar or disturbance of any kind, about the boiler.

Correspondence Re Graded Certificates

A SUGGESTION

The Editor:

Sir: The controversy re graded certificates is now on and I think it would be a good plan for the publishers of this Engineers' Journal to request all writers to give their names and address for publication. Readers would give more respectful atention to letters if they knew the standing of the writers. "Justice" and "Chief" may be my next-door neighbors and from the composition and phraseology of their letters I gather that they are, "from an engineer's standpoint," educated and experienced men. Sign your name, boys, it will do you and others good. You and I are willing to meet the board or any one else in a fair field and no favors asked. The graded certificate has been made law for better or for worse, according to individual opinion. I was seretary of the C.A.S.E. in this city when the full examining board went from end to end of the province to meet all the unions, lodges and associations of engineers and get first-hand opinions. We were asked to put our views in writing and did so, as far as we could from the mass of conflicting opinions. The Examiners had all this material before them when they sat down to frame a law. And from all this material, like a bench of judges, they framed the present law, and who were better qualified to do so? Now, no law ever yet made by man could suit all parties, and even laws made by God do not suit some people. Personally, I propose to support the board in their efforts to better the engineer and will assist with what knowledge and experience I possess to help my brother engineers to get a 1st class certificate.

I have much more to say, but will leave it till the next issue.

London. Ont.

D. F. Campbell.

A GOOD SOLUTION

The Editor:

With reference to the letter, "A Reply to Justice," which appears in your issue of Nov. 20th. I would like to express an opinion about a point brought forward in that letter. The writer says he was given to understand that it is not essential for a man to have all the different formulae in his mind, and I think we will find that will be the case. The rule regarding books and papers in the Board of Trade Examinations for marine engineers in the United Kingdom reads: "candidates are prohibited from bringing into the examination room books or papers of any kind whatever. The slightest infringement of this regulation will subject the offender to all the penalties of failure." Many of the questions have the formula given with them. I submit three as an example, and I think we will find in our examinations for a stationary engineer's first-class papers that the examination will have something the same form.

Question 1:

The piston is 60 in. diameter, steam 32 lbs. per sq. inch, length of crank 18 in., diameter of shaft 12 in. What is the stress on the shaft per sq. inch?

$S = \frac{5.1\ Wa}{d^3}$. S = stress. W = total pressure on piston. a = length of crank. d = diameter of shaft.

Question 2:

A safety valve 6 in. diameter has a spiral spring 5 in. diameter outside, ⅞ in. thickness of steel. What is the pressure per sq. inch?

$\frac{8000\ S^3}{d^3}$ = total weight. S = the thickness of the steel d = the diameter of the spring from centre to centre.

Question 3:

With double butt straps and double riveted, what would be the safe working pressure of a boiler, whose diameter is 11 feet and the thickness of the shell plates ⅞ in. ?

The safe working pressure may be found approximately by taking the thickness in inches, shifting the decimal point three places to the right and dividing by the diameter in feet.

Dryden, Ont.

Arthur Smith.

A REPLY FROM JUSTICE

The Editor:

Adverting to Chief's reply to my letter re. graded certificates, I do not see that I can add much to what I have written. My point was that the new act does not give any encouragement to young engineers, and this point was corroborated by T. H. Fenner in Nov. 5th issue.

I also called your attention to the clause which states that an engineer in charge of a plant of 150 B.H.P. or over is entitled, if he holds a 1919 certificate, to continue until he changes his position, and made the suggestion that engineers who receive a grade lower than what the act calls for should sit for an examination. etc

Chief states, many of the engineers who have been influential in the securing of this act are placed in an embarrassing position by its wording, and he refers to engineers in charge of plants of unlimited capacities who know the ins and outs of engineering from A to Z. etc. In this he is quite correct, and I agree with him. But are there not some so-called engineers in charge of plants who are not so well informed and qualified? Hence, if a special examination was held as I suggested, the engineers referred to by Chief would be granted a 1st class, and those who I had reference to would not.

I feel certain that the examiners will not turn down a man who knows engineering from A to Z, even if he is not well informed in trigonometry and calculus. And as a first-class is only to be granted by an examination, and to conform with Section 15a, I still think this is the best solution.

Trusting this will give Chief a clearer idea of what I meant in my last letter and that he, being a gentleman, will withdraw the remark that I am a Bolshevik.

Justice.

A WORD FROM JUSTICE THE SECOND

The Editor:

In your issue of November 20th I have been more than amused reading the letter of one who calls himself "Chief."

This man seems to think that a man who knows engineering from A to Z should have a first-class certificate granted him: yes, so do we all, but, how is he going to prove this to others? Have others to accept his word for it? Most certainly not! Let him sit down with the other chief engineers and prove his knowledge in a straight-forward manner. The majority of chiefs think they know their own plant, but, allow me to inform my honorable friend that very few of the chiefs in one of our large cities will enter into a debate or argument, and if possible, will shun the engineering topic entirely. What is the reason? Because in their own estimation they know engineering from A to Z, while at the same time they are merely holding their positions by bluff. Now the Government of Ontario has called their bluff and they are shaking in their shoes and, will call out in vain as they have yet to prove to the Government of Ontario through their qualified examiners, what they really know. not to their employers as "Chief" would like to emphasize in his letter as it is an easy matter to convince or lay down facts to one who is entirely ignorant of engineering in any of its branches.

Let justice be done to everyone; with no red tape, no string pulling, and no influence connecting the present-day engineers with the gaining of first-class certificates on and after January 2nd. Let all chiefs and engineers prove their ability and show that they are worthy of holding such papers by gaining the qualifying percentage to the questions set forth to them on or after the aforementioned date. By so doing they will have demonstrated to those in authority that they are really masters of their profession.

Justice II.

Laying Out Boiler and Engine Foundations

This Article Takes Up the Actual Construction of the Foundation From the Excavation to the Mixing and Placing of the Concrete

By T. H. FENNER

HAVING run the lines and located all the points of the foundation, the next operation will be the excavating.

Don't forget that when you are putting in and squaring up the forms for the concrete, you will need room to work so make the excavations about six inches wider than the form will be. In the case of a deep foundation, the width of the excavation would be governed by the room necessary for a man to work in. The nature of the ground has to be considered carefully. If of a wet, clay-ey nature, liable to slip, it will be necessary, in ordinary foundation work, to dig the trenches for the forms two or three feet wider than the width of the form. Either that, or the sides will have to be sheathed with planking to prevent slipping. If the foundation is a deep one in this sort of ground, sheathing is an absolute necessity. However, if the ground is dry clay, soft rock, or any solid material, there will be no need to consider methods of retaining it. It will just be a straight digging proposition.

You will now, or before this time, if your source of supply is a distant one, have considered the amount of material required for concrete, and made arrangements to get it on the job. Let us see how much concrete we shall need, and how much of each of the different constituents that are used in making it.

Estimating Quantity

It will be necessary to figure up the number of cubic yards of concrete in the whole foundation. Then having determined the proportion of the mixture of cement, sand, and stone, determine the quantity of each. Get them delivered as close to the job as possible, always taking care that the cement is put in a perfectly dry place.

First of all, to estimate the total quantity of concrete. We have 2 side walls, the centre wall, back wall, bridge wall, and front wall foundations. The side wall foundations are 20 inches wide by 36 inches deep by 22 feet long. That is $1.66\times3\times22\times2=220$ c.f. nearly.

The centre wall, say, 24 inches wide, but the same depth, gives $2\times3\times22=132$ c.f.

The back wall, 20 inches wide by 17 feet long by 3 feet, $1.66\times17\times3=84.66$ c.f.

The bridge wall, $1\times17\times3=51$ c.f.

The total amount of concrete will be $220+132+85+51+51=539$ c.f.

This is roughly 20 cubic yards of concrete.

Now comes the question of the proportions to be used. For foundation work, using stone of 1½ to 2 in. sieve, the mixture should be 1 cement, 2 stone, 4 sand, and for larger stone, 1 cement, 2½ stone and four sand. Suppose we conclude to use the latter proportion: We have a total of $1+2\frac{1}{2}+4=7\frac{1}{2}$ or 15. Now the cement will be $\frac{1}{2}\div7\frac{1}{2}\times20$

$$=\frac{20}{1}\times\frac{2}{15}=\frac{40}{15}=2\ 2\text{-}3\text{ c.y.}$$

The stone will be $\frac{2\frac{1}{2}}{7\frac{1}{2}}\times20=\frac{5\times2}{2\times15}$

$20=6\ 2\text{-}3$ c.y.

The sand will be $\frac{4}{7\frac{1}{2}}\times20=\frac{4}{1}\times\frac{2}{15}$

$\times\ 20=10\ 2\text{-}3$ c.y.

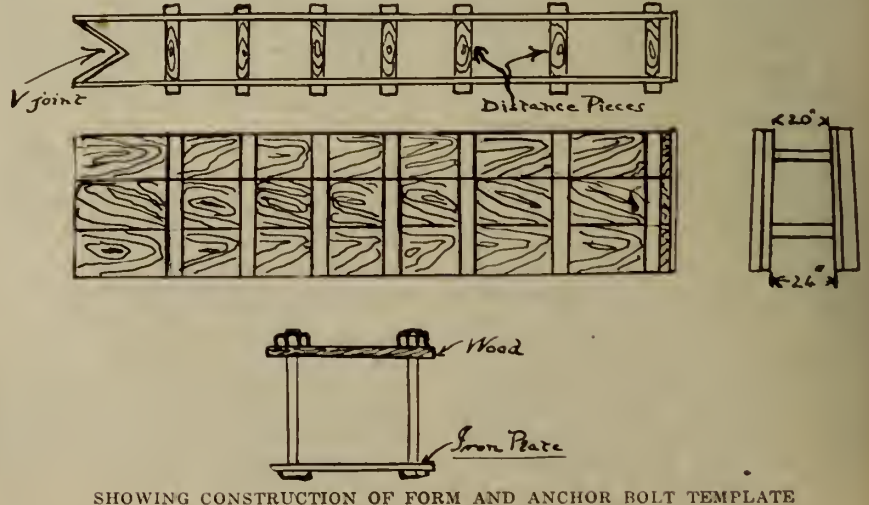
$2\ 2\text{-}3+6\ 2\text{-}3+10\ 2\text{-}3=20$ c.y.

That is taking the proportion by volume. A cubic yard of concrete weighs, roughly, 3,350 lbs., the specific grayity being 2. Sand weighs about 2,430 lbs. to the cubic yard, and common stone 4,239 lbs. Cement weighs about 2,187 lbs. to the cubic yard. Cement is always ordered by the ton, but sand and stone or gravel by the cubic yard.

When the men are fairly started on the excavation work get the carpenters busy on making the forms. At the same time get the board that the concrete is to be mixed on into the boiler room. This should be a good flat board about 8 feet square, round which about eight men can work comfortably. I am assuming that you have no mixer. Arrange the runways for the bringing of cement, sand and stone to the board, and then determine how much you will mix in each batch. This will, of course, be governed by the size of the board and the number of men available. Wherever possible you should get two boards, and have a gang mixing and a gang pouring.

However, we are not yet ready for mixing and pouring. The excavating has been started, and you have got to keep the ground clear, which means you must wheel the stuff away as fast as it is thrown out. The distance you have to wheel the stuff out will determine the number of barrows you need. If there is room for a horse and cart, use one, because that is the quickest and cheapest way to handle the stuff. The horse and dump cart take as much earth away in one load as six men with wheelbarrows, and is quicker covering the distance. Generally speaking, in ordinary ground, four men digging can keep three men busy wheeling. They will be too fast for three men at the beginning, but as they get down deeper the wheelers can handle them all right. Of course, if the stuff has to be wheeled very far, you need more men, working in relays. That is, where the team is a benefit.

Having started on the excavation work and found a place to store your material, the next thing is to get the carpenters down to make the necessary forms. For foundation work, only the cheapest forms are necessary. It should also be arranged so that the same forms can be used more than once. For instance, the side walls and centre wall are all the same length, and so are the back, bridge, and front walls. The side walls are 22 feet. The carpenters should get one inch boards, twelve feet long. For the side walls, which are 22 feet long over all, but only about 18 feet between the back and front walls, two forms twelve feet long and two six feet long should be made. These four forms should be enough for the whole job, unless you have a big enough gang working to run the whole foundation at once. This is unlikely. In cases where the stationary engineer is handling the job himself, unless he is rushed for time, too big a gang is a hindrance. It is different with a contractor, who has



SHOWING CONSTRUCTION OF FORM AND ANCHOR BOLT TEMPLATE

his foremen and sub bosses to handle his men, and is used to quick work. It pays him to get the job done and get his plant away. The proposition is different with the man who is going to erect the machinery as well as the foundation. You may rush all you like, but concrete has got to set, and you might as well let it do its hardening in such a way as not to delay the job. The best way is to get one foundation excavation made, say, one side wall, and get the men digging on another while the forms are set and the concrete poured in the first. The forms are merely 12 inch planks, laid edge to edge, and nailed to studding every two or three feet. Where points have to be made, as in this case, the end of the form should be closed with a V shaped piece, so as to provide a dovetail joint. Another way is to fill the form only partially at the end to make a scarph joint. By the time the forms are set, and the concrete mixed and poured, there will be enough of the second foundation excavated to enable a form to be put in, either a long or short one, and keep going on the pouring. The remaining part of the excavation will be carried on at the same time, and the third wall excavation started before the concreting of the second wall is finished. The first concrete will now be well enough set to enable the forms to be removed, and these forms can be used on the third wall, while the second one is hardening. In this way work can go on steadily, the concrete hardening as the work goes on. There need be no fear of the concrete not knitting where the joints are made, and the whole foundation will be one piece when finished.

Placing the Forms

Before placing the form in the excavation, go over the lines again, and check up the measurements. The lines may have been moved or broken during the digging out, and must be corrected before the form is set.

The forms are three feet deep, and the foundation is to be 20 inches wide. Make the forms 20 inches wide inside at the top, but spread them out at the bottom to, say, 22 inches or 24 inches. This will use up a little more concrete, but it makes the foundation stable. That is, it will stand on its own base. The completed form consists of two sides and two ends. Between the two sides, and coinciding with the studding, pieces of 4 in. square timber are nailed to keep the necessary width of opening. If the form is to be put end to end with a second form, that end will, of course, be left open. The ends of the forms are butted close together, and a board nailed to the outside, covering the joint, when in place.

The forms are put in the trench and nailed up in place. The usual practice is to place packing in the form of bricks under the corners to bring them to the desired height. They are then carefully levelled with a spirit level and long straightedge, and after that, must be secured. Here is a point that should be given attention. Don't forget that when men are dumping barrow loads of concrete into a form, they are far from gentle. Don't spare any pains in making the form secure. Brace it well from the walls of the trench so that it cannot move in any direction. Get the forms in proper alignment and all secure before a bucketful of concrete is poured. A little time spent in that way will repay itself in the long run. To ensure against the forms sinking, lay a couple of boards across the top of the form, resting on the ground each side of the trench, and nail them to the form.

The next thing to do is to place the anchor bolts which hold the columns. These must be placed in position and secured firmly. Measure off the distance along the line from the back or front of the boiler to the first column centre, and from there to the second column centre. Mark this on the side of the form for a guide. Then get your anchor bolts and template and place it in position. The template will be a simple piece of two inch board, with holes for the bolts drilled at the proper distance apart. A centre line will be marked on the template, which is placed in line with the mark on the form. The bolts are passed through a piece of flat iron about ½ inch thick, and wide enough to allow of the bolt holes being drilled. This is dropped down on the bolts to the bolt heads, and the template is nailed on top of the forms, after being accurately located. The screwed ends of the bolts are passed up through the board and the nuts put on to hold them. The lower part of the bolts and the anchor plate must be chocked off, so as to prevent moving. This is the simplest form of template.

The next step is the mixing of the concrete and pouring, which will be taken up in a later article.

NEW METALS FROM NEW FURNACES

Some details are now available of the manufacture in Great Britain of cupronickel originally undertaken for the production of small arms ammunition, and now continued on a large scale for industrial purposes. Research was instituted by Sheffield University into the production of satisfactory qualities and even the difficulties of using a large percentage of scrap metal were rapidly overcome. A special school was established for training casters in this and other non-ferrous metals. Electric furnaces are used for the melting of such metals, and in one Sheffield works there are over five such furnaces at work, ranging in capacity from 40 to 1,000 kilowatts. The resistance type of furnace has been adopted as best suited to metals which readily burn and vaporise. In this type the heating element consists of a trough lined with a granular material which becomes hot when current is passed throgh it. So efficient are these British furnaces that the actual metal losses in melting yellow brass scrap were less than one per cent. The current consumption varies from 300 to 350 kilowatt-hours per ton of yellow brass scrap melted. One of the 1,000-kilowatt furnaces melts brass at the rate of two tons per hour when supplied with 600 kilowatts, and is also used for remelting aluminum pig, taking three tons at a time and using 500 kilowatts. When melting zinc, the same type of furnace has a capacity of 200 tons per day, and shows only 0.024 per cent. of waste metal. These developments suggest that Great Britain intends to play a very important part in the wide field opening up for non-ferrous metals.

BOILER PRIMING TROUBLES

Priming is the technical name given to the passage of water along with the steam, from the boiler into the steam pipes, engines, etc. When occurring in a pronounced form it may be attended with very serious results, since the withdrawal of a large quantity of water from the boiler may lay bare the furnace, combustion chamber, or firebox crowns, thereby causing overheating and possible damage to the boiler, engine cylinders, pistons, and so on; and perhaps loss of life through an explosion. The cause of such phenomenon may be due to (1) undue and sudden fluctuations of steam pressure or demand; (2) an absence of an anti-priming pipe; (3) a partially choked anti-priming pipe; (4) undue forcing of a boiler in the matter of steam raising; (5) impure feed water; (6) the presence of sediment or grease in the water or an excess of lime or soda, or other materials injected into the boiler with a view to the reduction of mud or scale, and (7) to the water level being maintained too high.

Warren Webster & Company announce, with regret, the resignation of Mr. Frank G. Phegley, who severs his relations with the Webster organization after nine years of valuable service as manager of their Cleveland office, in order to enter the professional field as consulting engineer in heating and ventilating work. Their Cleveland office will be maintained at the same location, No. 706 Rose Building, but will hereafter be under the direct management of the home office. Mr. Clyde W. Colby, who has an extensive acquaintance with the heating trade in Northern Ohio, has been appointed as Cleveland district manager, and will have associated with him as assistant district manager, Mr. William Roebuck, Jr., who has been a part of the home office sales-engineering organization for the past nine years.

A Fourth-Class Certificate Requires——

A Candidate for Fourth Class Certificate Should Have a Knowledge of the Following Subjects. The List is Based on the Requirements for Examination and is Authoritative

By W. F. SUTHERLAND

He should have a fair knowledge of addition, subtraction, multiplication and division. This does not mean speed in calculation, but sufficient familiarity with arithmetic to work out problems met with in everyday life. This does not include fractions, either vulgar or decimal.

He should be familiar with the various types of boilers, should be able to describe them and to tell wherein they differ. This does not mean that he should have a knowledge of the strength of boilers or of their parts. The boilers with which he will have to deal may be given as follows:—

Horizontal return tubular.

Vertical fire tube, both dry tube and submerged tube types.

Water tube boilers of various types.

He should be able to describe the functions of the various parts of these boilers, manholes, shells (for fire tube boilers), drums (for water tube boilers), etc.

He should be able to describe the method of using man and hand-holes, their making steam-tight, and precautions to be observed in opening up a boiler.

He should be able to describe the general construction of and the functions of tubes. In addition, he should know how to clean tubes and why, how to expand them and to plug them when necessary.

He should be familiar with the function performed by the blow-off, how, when and why to use it. This is in the regular operation of the plant, and he should also be acquainted with the necessity of securely shutting the blow-off connection when working inside the boiler and when other boilers form a portion of the plant.

He should be familiar with the various types of safety valves, such as spring-loaded, lever-loaded and dead-weight. He should also be familiar with the functions performed by fusible plugs.

He should be familiar with the function performed by the safety valve and should know how to maintain it in a safe operating condition. Above all he should know that the escaping steam should have a free and unobstructed passage without hindrance by other valves or obstructing material. In this connection also he should realize that additional weights, monkey wrenches, etc., should never be hung on a lever safety valve, and that blocking the valve is a sure way of stepping heavenwards.

He should also realize that if safety valves are not operated once in each shift someone is neglecting his duty, and that valves so neglected are apt to make for trouble some day.

He should be familiar with the functions performed by the main steam valve and non-return stop valve in the securing of safe operation, and should know how to operate them in the cutting in and out of boilers. He should also be acquainted with the fact that such valves should be locked when anyone is working in a boiler down for repairs or cleaning, and that the person in the boiler, as the one most concerned, should carry the key.

He should be familiar with the construction of and the functions performed by the water-gauge and try cocks. He should know that the best way to keep try cocks in condition is to try them at least once in each shift. He should know how to take care of spare gauge glasses and how to insert them and make other necessary adjustments.

He should be able to read a steam gauge correctly.

A knowledge is desirable of the functions performed by and method of operation of feed-water heating apparatus such as open and closed heaters.

He should be familiar with the function and operation of feed-water pumping equipment, whether pumps or injectors.

He should be able to give intelligent answers as to the control of the feed water entering a boiler.

He should be able to tell what safety precautions are to be observed when cleaning a boiler and should be able to describe how to go about the cleaning itself.

He should know that it is unwise to attempt repairs to any vessel or packing when under pressure.

He should know what to do in the event of low water, or other emergency conditions likely to be encountered in the boiler room.

He should be familiar with the construction and operation of the different parts of a boiler setting, and should know the functions performed by each. These parts would include ash pit and doors, grates, stationary and dumping, bridge-wall, combustion chamber, dampers, flues, breechings and stacks.

He should know how to maintain proper combustion conditions in so far as an air supply and regulation are concerned.

Indicating and recording instruments are of much use in the boiler room and the fireman ought to be familiar with their use. Aside from the steam gauge and water gauge, of which a very full knowledge is required, the fireman ought to be acquainted with the draft gauge and other instruments of similar type. Their use in controlling firing conditions should be known.

He should be familiar with the functions performed by the proper method of lubrication and the general operating features of bearings.

He should be familiar with the construction of pipe runs and their joints and packing, the functions each of the above perform should also be familiar to him, as well as the maintenance features incidental to their care. He should know, for instance, how to properly pack a joint and how to draw up the bolts holding flanges or fittings together. He should also be familiar with the construction and function of fittings in general and should know how to care for valves and how to operate them.

Traps and separators come under the care of the fourth class engineer, and he should know how to take care of them, and should know what they are for and how they function.

The above is only an outline of some of the most essential information which the fourth class applicant should know. Many other features of the boiler room are familiar to firemen working in the particular plants where these are installed, and it is to the advantage of the fireman to know something about them. The applicant's experience will necessarily affect the type of question asked him, and, where, in view of this experience, he is able to answer questions with respect to the particular equipment in his care this will certainly count greatly in his favor. For instance, if he is firing in a plant where fuel oil is used, a knowledge of the functions and operation of the apparatus employed would be of help to him.

WELDING REPAIRS TO WATER WHEEL

An electric welding repair job that is of considerable interest to the power plant operator and the mechanical engineering field in general, is shown in the accompanying illustration. In the initial construction of these water-wheels, difficulty has frequently been experienced in obtaining a firm and rigid connection where the vanes join the supporting rings. Generally speaking, the vanes are steel castings that are placed in position in the sand mold so that the molten iron will flow about the edges and form an integral casting. However, the result has often been unsatisfactory, as the subsequent expansion and contraction of the vanes and the rings causes a looseness in one or more of the connections. The peculiar construction of the vanes makes it difficult to use the oxy-acetylene process in uniting the vanes to the retaining rings, and relatively poor success has, so far, been obtained by the use of the electric process, when working together steel and cast iron. However, the St. Lawrence Welding Co., of Montreal, who accomplished the repair on the wheel here shown has effectively formulated a special flux that overcomes former difficulties, and the vanes can be rigidly secured to the cast-iron rings, by means of the electric arc method, so that the force of a sledge upon any of the vanes will not produce the slightest defect in the welded joints. The cut shows the work immediately after welding; the rough appearance of the added metal was subsequently removed by grinding, leaving a smooth fillet weld in from the outer edges. Water-wheels treated in this way have shown greater efficiency after welding by this method.

BUILDING UP A WATERWHEEL RUNNER BY WELDING.

THE "NO-REPAIR" AEROPLANE

One of the accidents of war led to a very convincing proof of the remarkably high standard of British engineering work. A British fighting aeroplane was delivered by the makers in September, 1917, and immediately put into commission. After a busy period of war service it was forced to land in Holland. The pilot was interned and the aeroplane was bought by the Dutch Goxernnment. Since then Dutch officers have flown it continuously, but it has never been repaired or renovated even in the slightest detail. Not even the "dope" on the wings has been renewed. This machine is still in service, and is very popular with the Dutch pilots.

THE DAM AT BASSANO, ALBERTA, SUPPLYING WATER TO EASTERN SECTION CANADIAN PACIFIC IRRIGATION BLOCK

By FRANK C. PERKINS

The accompanying illustrations show the great Canadian concrete dam at Bassano, Alberta, supplying water to Eastern Section Canadian Pacific Irrigation Block. The purpose of the dam is to raise the water of the Bow River to such a level that it will run out along the main canal. It is of interest to note that the main canal is 5 miles in length and there are some 475 miles of secondary canals and over 2,000 miles of distributing ditches supplied from it. The dam, which was begun in 1910, brings under intensive cultivation 440,000 acres and directly affects the settlement of over 1,000,000 acres of land of great fertility, which will, undoubtedly, become one of the greatest diversified farming and stock-raising regions on the North American continent.

The magnitude of this engineering feat is made clear from the fact that the dam has a total length of 7,014 feet and the spillway portion of dam, crossing the Bow River, has a length between abutments of 720 ft. The height from floor to the over-flow crest is about 40 ft., above which 11 ft. of water is retained by 24 sluice gates, operated by electricity.

It is stated that the spillway contains some 42,000 cu. yds. of concrete and 2,500,000 pounds of reinforcing steel. The dam will hold in check 4,000,000 tons of water, and the discharge into the main canal will be 3,800 cu. ft., equal to 100 tons of water per second. The Bassano dam illustrates the latest construction in concrete structures of this type as built by modern methods.

Recommends Coal as a Fuel

THE possibilities of developing power in Alberta are carefully analyzed by James White, of the Commission of Conservation in a paper now published, but read before the Industrial Congress at Calgary.

While a little apart from the subject, it is interesting to note that the factories of the world, including electric lighting and street railways, use 75,000,000 horse power; the railways of the world, 21,000,000, and the shipping of the world, 24,000,000, or a total of 120,000,000 horse power. Of the 75,000,000 horse power used in factories and general industrial and municipal activities of the world, about 13,000,000 is used in the United Kingdom, about 29,000,000 in United States, and 6,000,000 in the British Dominions.

There has been more or less of a popular belief, or illusion, that the gas wells of Alberta were the greatest producers of power, and would continue to be. This conception may have come to pass from several reasons, and no doubt the rather extravagant claims of some of the publicity exploiters of the various centres have much to do with it.

Alberta has a great power proposition. This can be proved in several ways. She has, in the first place, 87 per cent. of the coal deposits of the Dominion, a splendid gas supply with a very high B.T.U. grading, while the waterpower of Alberta is by no means lacking.

The report of Mr. White makes it very plain that he considers that the greatest prime mover that Alberta can develop successfully is found in the steam-electric plant. Water power, owing to high labor costs, is laboring under a heavy, permanent handicap. Gas is an uncertain quantity regarding permanency, and depending on it might lead to serious losses. Regarding coal as a source of power, the report says, "Now, the great source to which Alberta must look for power is her coal. During recent years, the great advance made in the art of the production of steam power is phenomenal. This advancement has given coal, as a prime agency for power development in competition with other prime agencies, almost a premier position. Those interested in the furnishing of power on a wholesale scale in Alberta must make their research into, and selection from, the achievements made in recent years in the field of power produced from coal."

The Coal Strike

WHILE the Eastern and Western provinces of Canada are independent of foreign countries for their supply of fuel, the central ones, particularly Ontario, are not so fortunate and depend on our neighbor to the south for coal. It is fortunate, indeed, at the present juncture that Ontario has developed her water power resources to their present extent, but fuel for heating and, to a less extent, for power, is required in large quantities.

The industrial troubles prevalent in the United States thus have a direct bearing on Canadian industry, and while escaping more lightly than the United States, heatless days and lightless nights, at least to the previous war-time extent, are an unpleasant possibility. It is, perhaps, idle to talk of economy and conservation when no fuel is available, but while our present stocks are still of an appreciable, although rapidly diminishing size, any slight economies possible in the heating plant or power house are of an immense value. The engineer best knows how to operate his individual plant at its best efficiency, and it is idle to enumerate the many ways in which coal may be husbanded.

And when plentiful supplies are again available it is still of importance that rigorous care be exercised in maintaining the power plant at its highest efficiency. Together with making the best of equipment on hand, the chief executive officer and the engineer might well have a session or two together, discussing ways and means of improvement.

In no single way can money be better spent than in purchasing indicating and recording instruments, together with other plant equipment not, perhaps, essential, but greatly conducive to economy.

The question of fuel economy has a national bearing as well as a direct monetary advantage. At the present rate of exchange imports of any kind have an adverse influence, and when fuel is unnecessarily wasted it simply means that the restoration of normal conditions is made that much more difficult.

WIRELESS AT THE RATE OF 200 WORDS A MINUTE

Remarkable Developments Have Taken Place — Messages Sent Over 12,000 Miles

A PAPER on "Recent Progress in Wireless Telegraphy" was read before a recent meeting of the E. I. C., and the speakers was J. O. G. Cann, chief engineer of the Marconi Wireless Company of Canada, in Montreal. During the address Mr. Cann spoke on the widespread use of wireless by the Germans and the enterprise of the British and other allies in the destruction of many stations in various parts of the world that had been utilized for enemy war purposes. Mr. Cann outlined the different systems now in use, describing briefly the operation of each, stating that the spark method of the Marconi Company was the one generally used throughout the world. Some conception of the efficiency of wireless may be gathered from the fact that signals from Carnarvon, in Wales, have been regularly copied at Sydney, Australia, a distance of 12,000 miles. Mr. Cann read two of these messages that had been transmitted during the period of the war.

Wonderful advancement has also been made in wireless telephony, and sets are now available which will permit of telephonic speech from one airship to another, or from the plane to the ground. Sets are also made for conversation between ship and ship. Mr. Cann also spoke on the progress of direction finding and the advantages that had been derived by its use in minimizing or eliminating many of the Zeppelin raids over France and England. This feature was also extensively used in locating enemy submarines and subsequently destroying them. Some idea of the progress of wireless may be had in the speed that is now possible in transmitting messages. The hand-sending method, with a speed of about 20 words per minute, is being replaced by apparatus with a capacity of over 100 words per minute, and special machines are now under construction, at Montreal, that will be capable of transmitting 200 words per minute. Signals from this new device will be transferred direct to the land circuit and from there taken off on a tape passing through a printing telegraph. Samples of these messages were on exhibit, and it is interesting to state that one of these was recorded when the operator was absent from the office. In addition to the address, Mr. Cann had with him some modern wireless equipment, and illustrated, with a number of slides, some of the essential mechanism of a wireless station.

Cyrus W. Field

WE are all too apt to pass over the achievement of the man who, while not an inventor himself, yet by his persistency and vision of greater things to come, makes possible, in a commercial sense, the fruit of some other person's inventive genius, to the everlasting benefit of mankind. Of such a type was Cyrus W. Field, the man to whom more than to anyone else the successful conquering of the Atlantic ocean was due, and who, after many unsuccessful efforts, succeeded in laying the first Atlantic cable.

It seems most fitting that the close of the one hundred years that have elapsed since his birth, November 30, 1819, should mark the beginning of a new era in which the status of wireless telephony and telegraphy has reached a high state of perfection through the travail of the last few years.

His early years were marked by nothing of startling import and were devoted to the accumulation of a fortune modest in these days, but of considerable size at that time. At the age of 34 he had amassed the tidy little sum of $250,000 and purposed retiring from active business life.

Ten years before Morse had succeeded in establishing telegraphic communication between Washington and Baltimore and Field's interest was aroused in the possibilities of the submarine telegraph through a meeting with N. Gisborne, an engineer who proposed laying a cable between St. Johns, Newfoundland and the United States.

Visions of retirement were abandoned in favor of an active attempt to lay an Atlantic cable which would put Europe into communication with the United States. And while no claim can be made that Field was the first to conceive of the idea of laying a cable under the Atlantic, he was the man who enlisted the capital on both sides; of more importance still, he furnished the abiding enthusiasm necessary to achieve success after three costly failures.

The first attempt was made in 1857 and when 260 miles from Valentia Bay, Ireland, where the start was made, the cable parted and sank. The second attempt made the following year met with a partial success for the cable was successfully laid between Newfoundland and Ireland amid much rejoicing. Twenty-six days after its first operation this cable in turn failed, ruined by the ignorance of the engineer in charge, a current of high potential being used.

It was not until 1865 that another attempt was made. Field by this time had some difficulty in securing the necessary funds and so 'tis said made somewhat of a nuisance of himself amongst his friends. The Great Eastern was employed as a cable ship and the third attempt met with failure when 1,062 miles had been laid and when the cable ship was only 600 miles off the shore of Newfoundland.

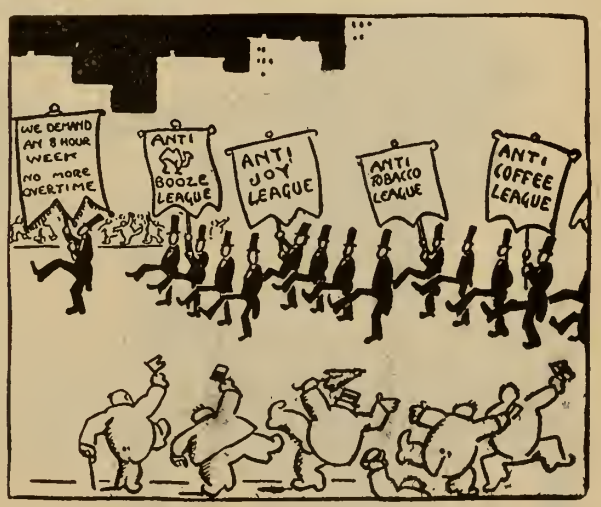
The final attempt was made the following year and not only met with success but the broken cable of the year before was successfully lifted, spliced and terminated on shore.

The interest aroused in these attempts may be estimated by the names of the men who lent encouragement and assistance to the enterprise. Michael Faraday and Lord Kelvin, then Professor W. Thomson, were among the English scientists interested with Maury and Morse in the United States. Thackeray and Lady Byron were stockholders.

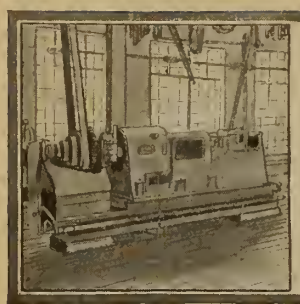
McCarthy's "History of Our Times," says:—

"He was not a scientific man; he was not the inventor of the principle of inter-oceanic telegraphy; he was not even the first man to propose that a company should be formed for the purpose of laying a cable beneath the Atlantic.

"But the achievement of the Atlantic cable was none the less distinctly the work of Mr. Cyrus W. Field than was the discovery of America by Columbus. It was not he who first though of doing the thing, but it was he who first made up his mind that it could be done, and showed the world how to do it, and did it in the end. The history of human invention has not a more inspiring example of patience living down discouragement and perseverance triumphing over defeat."



IF THE REFORM LEAGUES WOULD ONLY GO ON STRIKE!
—New York "World."



NEW POWER PLANT EQUIPMENT

THE NEW COPES REGULATOR

IN 1912, the Northern Equipment Co., Erie, Pa., brought out and patented the now well-known continuous feed principle of boiler feed control. They showed that water should be fed proportionately to and variably with the load. This gives a variable water level temporarily inversely proportional to the load; it gives a temporarily decreased feed on sudden increase in load; and a temporarily increased feed on sudden decrease in load.

Up to the year 1912 all feeding was intermittent in character and an absolutely constant water level was considered ideal. Now, however, opinion is unanimous with regard to correct feeding and authorities agree that the so-called "Copes Method" is correct in principle.

Since the introduction of this mechanical regulator changes have been made from time to time in the details of construction, the principle of feeding in the meantime remaining the same as that cannot be improved.

Fig. 1 shows the design of the new Copes control valve. It will be noted that the reciprocating stuffing boxes have been abandoned, and in their place we have a horizontal shaft which rotates very slightly, performing the same function as the old reciprocating rod. Naturally, this new design is very sensitive. The frictional resistance has been reduced as much as 6 to 16 pounds. It is now practically zero because the shaft rotates very slightly and the same part of the shaft is always in the stuffing box.

The valve, as will be noted, is of the balanced piston type. The weight on the valve lever exerts a constant closing force of 50 pounds on the valve piston at all times. A weight is used here rather than a spring, because gravity does not vary, whereas springs grow weak with age, corrode, stick, break, etc.

A vertical section through this valve is shown in Fig. 2, which displays the horizontal shaft, the stuffing box, the link work connecting the shaft with the piston valve, etc.

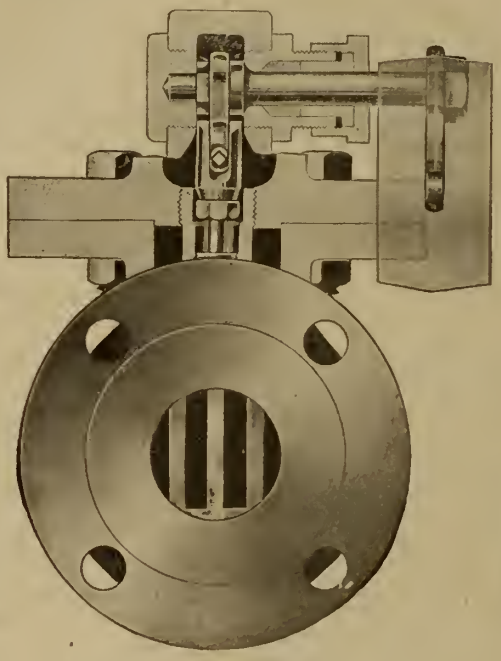


FIG. 2.

FIG. 3.

Another novel feature is shown in Fig. 3. The valve cap or bonnet can be unbolted and removed with fittings attached as photographed without removing the valve body from the pipe line. Any engineer will appreciate the great advantage inherent in this feature.

Fig. 4 shows how easily valve fittings are removed and renewed. A monkey wrench or any other kind of a wrench and a piece of flat stock are the only tools required. One of the seats is here shown after removal.

The assembled regulator complete is shown in Fig. 5. It consists principally of a heavy expansion tube—the long diagonal tube plainly visible in the illustration. This is known as the "thermostat." It is a straight piece of heavy metallic tubing 1⅛ in. in outside diameter. There is nothing about it to wear out, and as stated by the manufacturer it will "outlast any boiler." The top of the thermostat is connected with the steam space of the boiler and the bottom with the water space. Hence there is a water level in the thermostat corresponding with the water level in the boiler. It is this water level in the thermostat that determines the rate of feed. The tube lengthens and shortens with drop and rise of water level. The lengthening and shortening are caused by change in temperature of the tube as the water rises and falls. This expansion or contraction is amplified by means

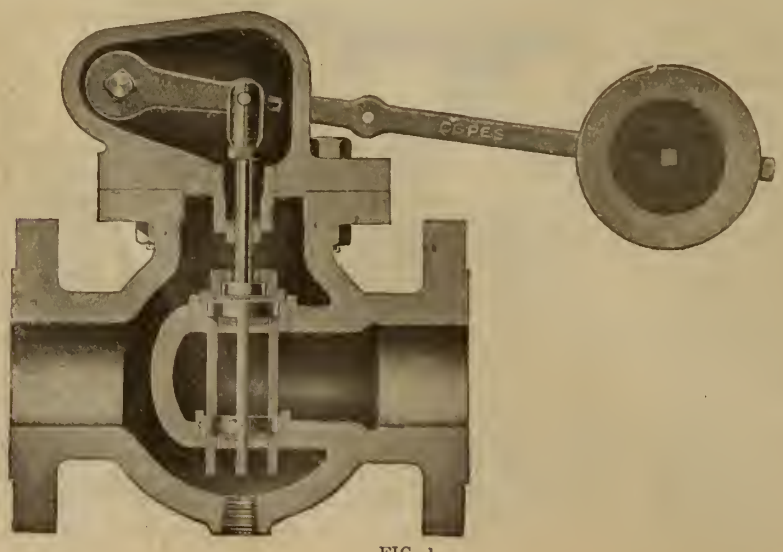

FIG. 1.

of the link work plainly visible in Fig. 5, and through the link work operates the control valve. All parts are simple, strong, heavy and rugged.

A Copes name plate has also been added as shown in Fig. 5. This has been done because regulators are usually placed on the level with the water in the drum, which is high above the heads of the operators or observers, hence the regulator is not noticed, and is often entirely forgotten even by the plant operatives. The Northern Equipment Co. want their regulator to be noticed and remembered occasionally—hence the name plate.

THE GAS TURBINE

In reviewing the development of the internal combustion engine in a paper read before the Institute of Marine Engineers, Mr. Charles Baxter touched on the problem of the gas turbine.

He remarked that the design of the internal combustion engine as it exists to-day does not seem likely to be radically changed since the principles are now well understood. Supercharging—i.e., forcing in an extra quantity of mixture or air at the end of the induction stroke—has been accomplished with a little success, but nothing very revolutionary has happened, the engine becoming complicated by the addition of such items as pump cylinders. From time to time suggestions have been made that a great advance in thermal efficiency might be obtained by combining the steam and the internal combustion engine. This idea occurred to the author several years ago, and he got out a simple design, which, however, eventually assumed such a complicated form that the idea was given up for the time being. Judging by test results, the engine of this form evolved by Mr. Still is likely to justify much of the confidence reposed in it.

The construction of a successful gas turbine is regarded as the next and final step in the development of devices for internal combustion. The great heat generated is the principal obstacle. One suggested arrangement consists of a chamber of refractory material in which combustion of the fuel takes place, the gases impinging upon buckets on a wheel, Pelton or de Laval style. In another, of a pulsating type, the action is that the chamber, being charged and fired, the gas rushes out of the jet, overrunning itself by inertia and drawing another charge of mixture after it through the flap valve. This action is rapidly repeated and is analogous to that which takes place in a gas burner turned very low.

The heat generated in these devices is, of course, very great, and the combustion is so continuous that no chance is given for cooling. In the ordinary type of high-speed engine the explosions, though very rapid, are intermittent so that the combustion chamber walls can be kept at a reasonable temperature, the

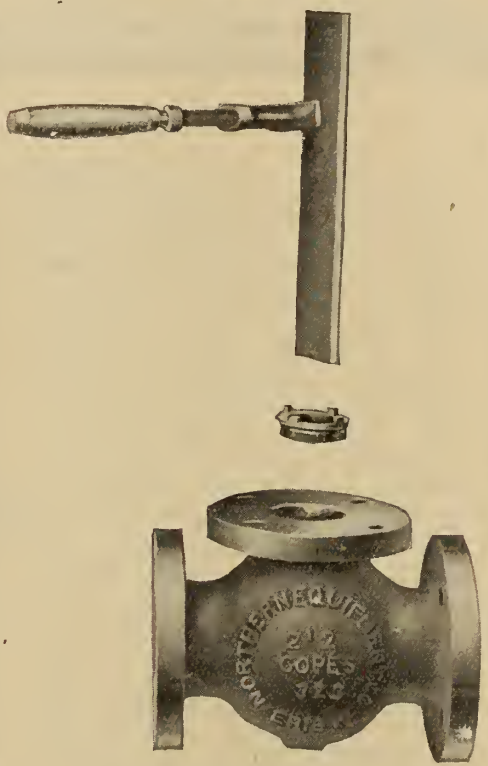

FIG. 4.

incoming cool gas being of great use in this direction. In a turbine design evolved by the author some years ago the gas was exploded in a chamber forming part of the casing. The resulting explosion did work by impinging on a chamber in the rotor, from which it escaped, being returned to the rotor vanes by means of a jet. The following charge under pressure scavenged and refilled the chamber. Such difficulties as holding the ported rings up to the rotor with just the correct pressure were surmounted by balancing the explosion pressure by means of a piston and fulcrum, the proportions being such that the pressure tending to force the ring from the rotor face was exactly balanced by the pressure upon the piston. These arrangements involved the use of turbo-compressors, the efficiencies of which are at present low, and even if a compressor of reasonable efficiency were forthcoming, there is no direct prospect of high combined efficiencies being obtainable. A combined gas and steam turbine, however, may do much to solve the problem, and the resulting machine, even if its efficiency was not such as to render existing prime movers obsolete, would undoubtedly be of some utility.

WIDENING THE RADIUS FOR ELECTRIC POWER

Recent achievements are increasing the distances of economical transmission of electric energy. In long distance transmission of electricity, high pressures or voltages are required—the higher the voltage, the lower the losses. For several years after long-distance transmission had been introduced, it was the practice to allow a pressure of approximately 1,000 volts per mile. It was found, however, particularly with distances of over 100 miles, that the distance allowed could be increased to as much as two miles per 1,000 volts. In other words, lines operating at about 100,000 volts pressure have been transmitting energy over distances exceeding 200 miles. More recently, lines operating at 150,000 volts have demonstrated their practicability; one of these has been in successful operation for over five years.

Electrical experts are of opinion that pressures of 220,000 volts are quite feasible and it is stated that "the handling of electrical potentials of 220,000 volts does not appear to involve any disturbing complications or uncertainties. In fact, the manufacturers do not recognize that any serious problem exists. Current design principles and materials now in ordinary use will be employed, the principal difference from present high voltage equipment being the greater amounts of insulation and the larger clearances required. The step to 220,000 is relatively no greater than that previously taken from 66,000 volts to 110,000 volts or from 110,000 volts to 150,000 volts. Certain of the manufacturers have already developed designs and assert readiness to undertake the commercial production of 220,000 volts. equipment on short notice."

The advantages of long distance transmission are of particular interest to Canada, where much of our water-power is found in large units and, to reach many consumers, it may be necessary to transmit the energy for a considerable distance. It is perhaps of greatest interest in connection with our abundant water-powers in the river St. Lawrence and in the area lying to the north of the settled regions of the Praire Provinces. It brings us closer to the possibility of making these vast stores of energy available within the settled portions.

FIG. 5.

The Operators' Point of View

SOLDERING FOR SHOP MEN

By Donald A. Hampson

Repair and maintenance work calls for ability to turn one's hand to many a trick that is foreign to every-day machine shop practice. Soldering is one of these tricks, yet a great many machinists are totally unfamiliar with such work, or have only seen it done, while still others despise such a method of making repairs. Soldering is not to be despised—it fills a very definite place—a good soldered joint is better than a poorly welded one. Many jobs that could easily be fixed up with solder are repaired by more expensive methods and by renewals. It is not a hard matter to make a good job of soldering if a few essentials are understood, nor is there required any expensive equipment.

Cleanliness is the first and last requisite for a successful job. The surface of the work must be mechanically and chemically clean. Mechanical cleanness is obtained by machining, filing, and scraping, together with the use of emery cloth that has not been contaminated with dirt and grease. Brass castings may be soldered on the surface if clean, but with cast iron it is necessary to cut or file off the outer surface or skin to expose the fresh metal. Cleaning should be carried a quarter of an inch beyond any part which the solder will touch so that by no chance will be work be retarded by the iron's slipping on to an unclean spot and thus carry dirt back to the joint being made.

The chemical cleanliness is obtained by the application of muriatic acid to the surfaces being joined. This provides for all necessary cleaning and prevents oxidation of the surface during the work. If it happens that the work pieces are galvanized or of zinc, then the commercial acid is used just as it is, but if any other metals are being handled (and the majority of jobs are such) then the acid must have dissolved in it all the zinc which can be absorbed by the acid; this "cut" acid is ready for use and is preferably prepared in small quantities so as to have always fresh acid on hand, and that as clean as such things can be kept which are being dipped into and exposed to air and swabs.

Sal-ammoniac is the most commonly used flux for soldering. Rubbing the hot iron over the surface of this is sufficient. Some men imbed a small amount of solder in a cake of sal-ammoniac and tin the iron by rolling the iron around in this hole, but it cannot be said to be good practice, for the hole gets constantly bigger and less efficient, finally getting bored clear through the cake, spoiling a chunk that at present prices may be worth two or three dollars. Tinsmiths invariably keep the surface of such a cake flat on top and use a holder or container that allows the greatest wear from the rather expensive chemical in use, a couple of movements per side of the iron is all sufficient.

Both the iron and the work must be "tinned" before any kind of a job can be done. This is the second great law of soldering. Oil, grease, dirt, all these prevent the tinning of iron and work, and they have to be removed. Tinning is the process of coating the surface with a thin layer of solder. So far as the work is concerned tinning may be done as a separate operation previous to joining the two pieces, or it may be done as a part of the work with the pieces clamped together. The iron, however, is always tinned before it is applied to the work. Soldering jobs are usually either joining two separate pieces together or filling up cracks, and in both cases it is preferable to tin the surfaces separately because when that is once done it is an easy matter to place more solder in the form of a bond between the two in whatever form or amount is desired.

Some materials resist tinning more than others. With those that offer greater resistance, patience is required to secure the coating, and the iron must be rubbed for some time on the surface before the result is secured, in the meantime keeping dirt and oxidation from accumulating. It is a help in tinning cast iron to coat the surface with a thin layer of copper by rubbing on blue vitriol, the surface having first been machined or filed.

Lack of heat is a detriment to soldering, in fact, most beginners fall down on this one point, and they try to solder with a cold iron and to make solder stick to a cold surface. The iron itself, however, should not be overheated; this is a common mistake around machine shops where the forge fire is used to heat, and where it is very easy to raise the iron to red heat. Soldering "irons" are made with a copper bit, and the red heat is injurious to copper; moreover the red heat burns off the tinned surface of the iron, necessitating doing this part of the work over again. A temperature of 400° Fahr. will melt solder, and there is no need to go a great deal above this.

The function of the iron is three-fold: to carry the solder to the work, to heat the work, and to distribute, or place the solder where wanted. If the iron consisted of the point only, it would fail in the first two functions, but it does not, and we have a large mass of copper back of the point which feeds the heat down to where it is used. Where sheet metal is being soldered the heat from the iron is sufficient, but where the parts are bulky it is preferable and quicker to heat the work in some sort of a clean flame, bringing the work up to about a straw color on steel.

Cast iron requires more heat than steel or brass. Aluminum requires a hotter iron than the other metals and also a special aluminum solder. Ordinary solder will not stick to aluminum; usually aluminum is soldered without any flux, or if any is used it is a specially prepared composition.

Separate parts being jointed by soldering require some sort of fastening to keep them together and in true relation until the bond has cooled. The work may be clamped on a surface plate or held in a vise, or it may be screwed and riveted together, or it may be wired.

The Editor:

In my opinion, the trouble with the setting of the valves, judging from the Indicator Diagrams, which appear in your issue of the 20th of Nov., is, that she opens too soon, closes too soon, and has too much lead. The remedy is put the eccentric back a little.

Dryden.

Arthur Smith.

R. M. Rook, who, for the past five years has been associated with the Metal Thermit Corporation, of New York, has been appointed general foreman of the St. Lawrence Welding Company. Mr. Rook has had a wide experience in welding work of every description, and was directly responsible for the successful repairs on what is considered the largest job yet accomplished by the thermit process. This was on the frame of a large stone machine, the weight of which was approximately 75 tons, requiring about 5 tons of thermit. Nearly seven weeks were required in preparing the mould.

The Marconi Wireless Company of Canada have removed their main offices from 173 William Street (the plant location), to 11 St. Sacrament St., Montreal, in the heart of the business district.

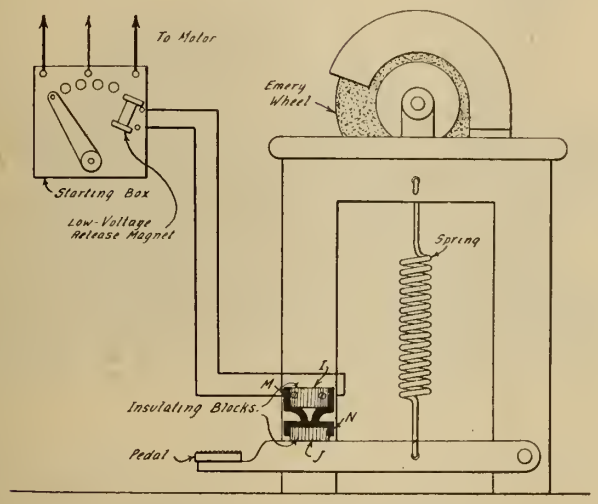
AUTOMATIC STOP FOR GRINDER

By Wilbur B. Burton

(Copyright. All rights reserved.)

GRINDERS are high-speed machines. The workmen often leave them running, after they have finished grinding their tools. The result is that the wear on the bearings is excessive, and considerable power is wasted.

An automatic grinder stop, Fig. 1, will eliminate these disadvantageous features. The scheme is, of course, applicable only on an individually-motor-driven grinder. A block of insulating material, I, was fastened to one of the legs of the grinder frame. To this block was secured two strips of sheet metal, M and M. Conductors were then wired, as indicated, from each of these contacting strips, M and M, to the low-voltage release magnet on the motor starter. The wires were fastened under the release-magnet binding posts, providing an electrical connection. If a short circuit or shunt is arranged across M and M, the low-voltage magnet is de-energized and the starting handle is released. It will then return to the "off" position, and stop the motor. To effect this short circuiting automatically, the pedal illustrated was provided. On it was mounted an insulating block, J, carrying a strip of copper, N.



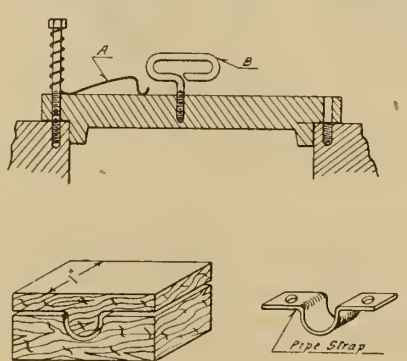
AUTOMATIC STOP FOR GRINDER

When a man wishes to start the grinder, he first steps on the foot pedal. This removes the short circuit from around the release magnet. He then starts the motor in the usual way. When he has finished grinding his tool, he must, of course, remove his foot from the pedal when he leaves the grinder. When he does so, N contacts with M and M, short circuits the low-voltage coil and automatically stops the motor.

TWO KINKS FOR THE POWER PLANT

The cover on a large gear box was held in place by two stud bolts; every time lubricant was put into the box the bolts had to be taken out. Ultimately, the cover was arranged as shown. A bolt extending above the cover for several inches was placed at one side of it, a piece of flat spring, A, and a spiral spring was placed as shown, also a hook at the centre of the cover. The other bolt hole was not used. When filling the gear box with lubricant, the cover was lifted by the hook and swung back, the grease or oil put in and the lid brought back. This was an improvement over the bolt arrangement.

Another simple kink is shown in Fig. 2. Cut two pieces of hardwood into the form shown and about one inch wide. To make a good pipe clip, all that is necessary is to cut a strip of fairly-heavy galvanized sheet iron about ¾ in. wide, place it between the wooden mold and force together between the jaws of a vise; trim the ends to the desired length and punch a couple of nail holes. The mould will only make one size strap of course. However, each mould will be good for thousands of straps.

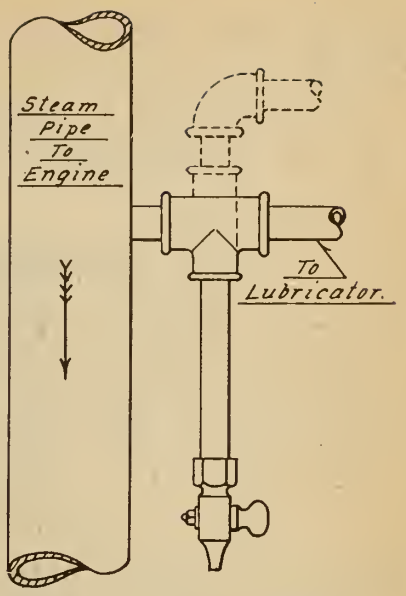


TWO POWER PLANT KINKS

SCALE TRAP FOR LUBRICATOR

A certain amount of sediment or scale from a pipe will often find its way into a lubricator with the result of closed up oil outlet holes. A simple way to overcome this trouble is to attach a drip, as shown in the sketch by the full lines, or as shown in the dotted lines. Some men seem to think that there is a better chance for the drip to catch the sediment when installed in the latter way.

J. ELLETHORN.



SCALE TRAP FOR LUBRICATOR

VANCOUVER CO. INSTALS A "GREAVES-ETCHELLS" ELECTRIC FURNACE

After an extensive investigation of the various types of electric furnaces and a visit to the U. S. Navy Yard at Puget Sound, where a 6-ton "Greaves-Etchells" furnace is in operation, the Vancouver Engineering Works, Ltd., Vancouver, B.C., has given an order to the Electric Furnace Construction Company for a "Greaves-Etchells" furnace.

The Dominion Bridge Company will utilize the plant of the St. Lawrence Bridge Company at Rockfield, for the building of the pulp and paper machines, a post-war development that promises to grow into extensive proportions. They also anticipate the building of a grey iron foundry for the making of the large number of castings that will be required in these machines and the turbo-equipment that they are now building.

Railway Board Reserves Decision.—On the application of the Canadian Manufacturers' Association, demanding that the express companies be compelled to carry electric light bulbs at first-class rates instead of double rates as at present, the Board reserved its decision. The express companies claimed that owing to the bulbs being very light, and occupying excessive space, they were not profitable to carry. The chairman said that he could not accept the idea that express companies should carry only what they wished. They were a public utility, and as such must perform the services the public demanded of them.

Nobel Plant is Sold.—The British Cordite Munitions plant at Nobel, near Parry Sound, has been sold to Mr. I. Cohen, a well-known merchant of Kingston. Nothing is known of what Mr. Cohen's intentions are with regard to the property, which includes buildings, machinery, trackage, etc.

First Oil Locomotive.—The first French locomotive to generate steam by the use of oil fuel has been tried out successfully, a heavy train being hauled without difficulty. It is understood that following this trial two hundred locomotives will be equipped to burn oil instead of coal.

Railway Board Decides Dunnage.—The amount of dunnage that will be allowed on agricultural machinery, implements, stoves, street cars, vehicles, etc., shipped in box or stock cars, has been fixed at 650 pounds by a judgment of the Board of Railway Commissioners. The allowance was formerly 1,000 pounds, and this has now been cancelled.

Van Horne Property Sold.—The Realty Service Company have sold the property on the north side of Van Horne Street, west of Dovercourt Road, to Soren Bros., tinware manufacturers, who will erect a new factory there. The property contained 332 feet, and the price obtained was in the neighborhood of $50,000.

Thos. Firth & Sons, Limited, Sheffield, Eng., announce that Mr. James A. Sherwood, who has for a number of years represented them in Canada, is retiring, and that Mr. John J. Coleman, who has had charge of the Toronto branch, has been appointed as successor to Mr. Sherwood. Mr. Coleman has just returned from Sheffield, England, where he spent the month of September.

No Coal From Ontario.—The Fuel Commissioner has issued an order prohibiting the shipping of any bituminous coal from Ontario without a permit from him. This order is to insure the supply of bituminous coal for Ontario needs as the commissioner feared that attempts might be made to ship some of the coal stored here to points outside the province.

Bridgeburg Gets New Plant.—The Reliance Manufacturing Company, with a capital of $500,000, will locate in Bridgeburg. The factory will be on Lewis Street, and the product will be electrical goods, such as fuses, switches, etc. The Brazil Motors Company, of Brazil, Ind., which is considering Welland, Port Colborne or Bridgeburg as sites for a factory, has arrived at no decision yet.

Black & Decker, Baltimore, have issued a new catalogue on portable electric tools, electric air compressors and special machinery. The catalogue is an excellent specimen of good typography and presswork. Besides the above-mentioned lines are drills, tapers, sleeves, etc. Black and Decker products are covered by the usual guarantee. The firm warns against having repairs made by unauthorized parties. The catalogue is being issued twice a year by this firm.

City of North Battleford, Sask.

TENDERS FOR POWER PLANT EQUIPMENT.

Sealed Tenders, addressed to the undersigned, and marked "Tender for Power Plant Equipment," will be received up to 5 p.m. on Saturday, December 6th, 1919, for two 250 H.P. Water Tube Steam Boilers, one sheet metal stack, 50" x 60', and a quantity of metal smoke flue.

Plans, specifications and all further information may be obtained on application to M. D. Cadwell, Supt. of Utilities, City Hall, North Battleford, Sask.

ROBERT FARQUHARSON,
City Clerk.

The City Hall,
North Battleford, Sask.,

NON-CORROSIVE

CYLINDER OIL

MANUFACTURED ONLY BY

E. H. KELLOGG & CO.

NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.

FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner yon lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

WANTED

Representatives to handle special line of British made "Elastic Steam Jointing Cement" (for all joints) and Iron Cement for casting, etc. Exclusive territory offered parties conversant with trade. Replies treated confidential. Apply Box 151, Power House.

WANTED — BY LARGE ONTARIO BOILER manufacturer, an experienced draughtsman, familiar with the designing of tubular, locomotive and stationary boilers. Write Box 153, Power House.

WANTED — FIRST-CLASS ENGINEER TO take charge of steam plant; prefer a man with knowledge of Detroit Stokers, also one who has had some experience with electrical machinery. Box 154, Power House, 143 University Ave., Toronto.

You Try This

When you desire any information on matters pertaining to the trade it will be gladly furnished free upon application through the columns of this paper. If you enclose stamped, addressed envelope we will also reply direct to you. Don't hesitate to ask us. We will do our best.

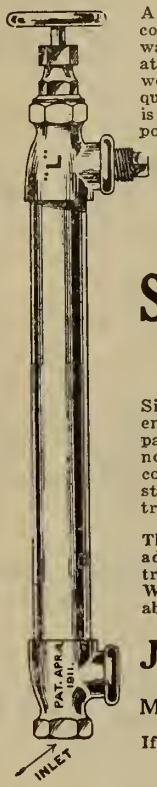
Power House Economy



A Steam Trap that saves coal by abolishing heat-wasting steam leakage, and at the same time does its work efficiently without requiring constant attention, is the trap you want in your power plant.

The Long Patent Steam Trap Fills the Bill

Simple, reliable and efficient. Has but one moveable part. Automatic — requires no valves except those which control the admission of steam to apparatus to which trap is attached.

The Long Trap has several advantages over all other traps. Protected by patents. Write and let us tell you all about it.

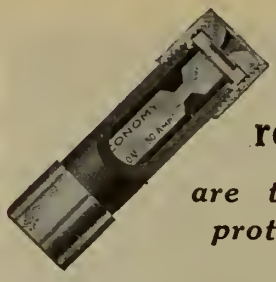
If your dealer does not sell it, write direct.

6



ECONOMY renewable FUSES

are the RIGHT fuses to protect YOUR electrical circuits

—because they afford the right sort of protection; their reputation lends assurance that you can safely depend on them for accuracy of rating and all-around efficiency in operation.

—because they cut annual fuse maintenance costs 80% as compared with the use of one-time fuses, owing to the fact that an inexpensive "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

—because it's the work of a moment to replace the link and renew the fuse.

—because a good sized stock of "Drop Out" Renewal Links always on hand represents but a small outlay. ***Write for Catalog 24***

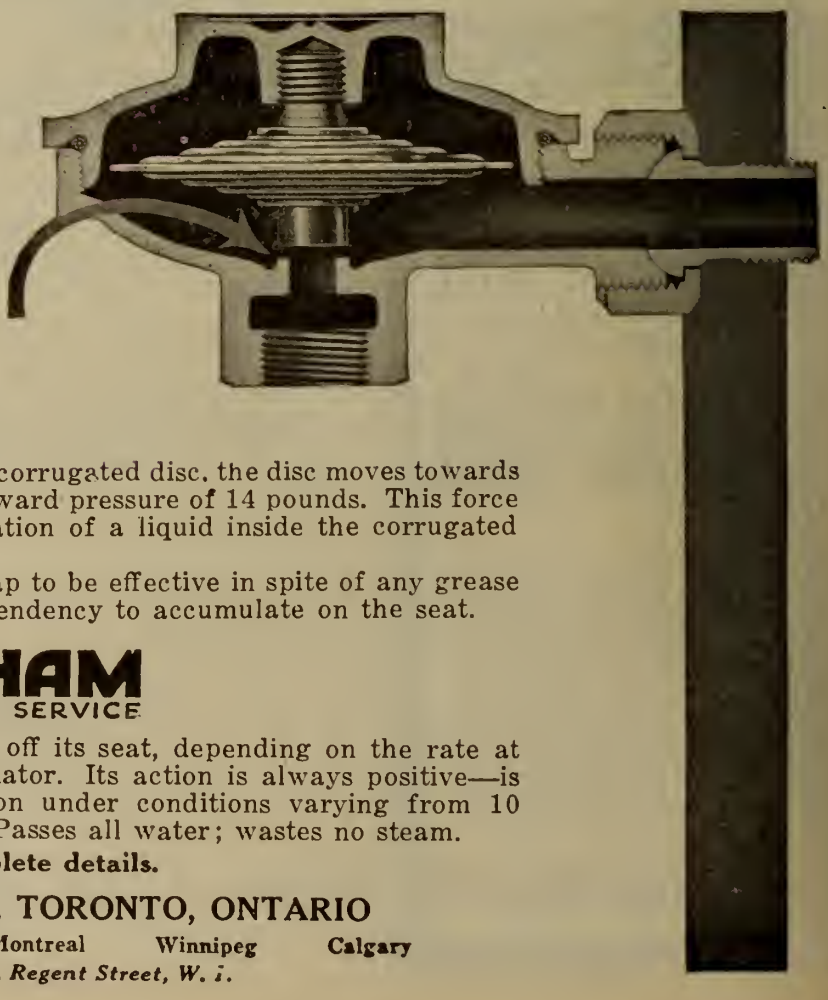
S. & C. HIGH POTENTIAL FUSES—TO 150,000 VOLTS

14 Lbs. Pressure downward



AS soon as steam strikes the sensitive corrugated disc, the disc moves towards its seat and exerts a maximum downward pressure of 14 pounds. This force is exerted uniformly by the vaporization of a liquid inside the corrugated disc.

This downward pressure causes the trap to be effective in spite of any grease and foreign matter which might have a tendency to accumulate on the seat.

The DUNHAM HEATING SERVICE

In action, the disc is alternately on and off its seat, depending on the rate at which the steam is condensed in the radiator. Its action is always positive—is never sluggish—and can be depended on under conditions varying from 10 pound pressure to 15 inches of vacuum. Passes all water; wastes no steam.

Write for complete details.

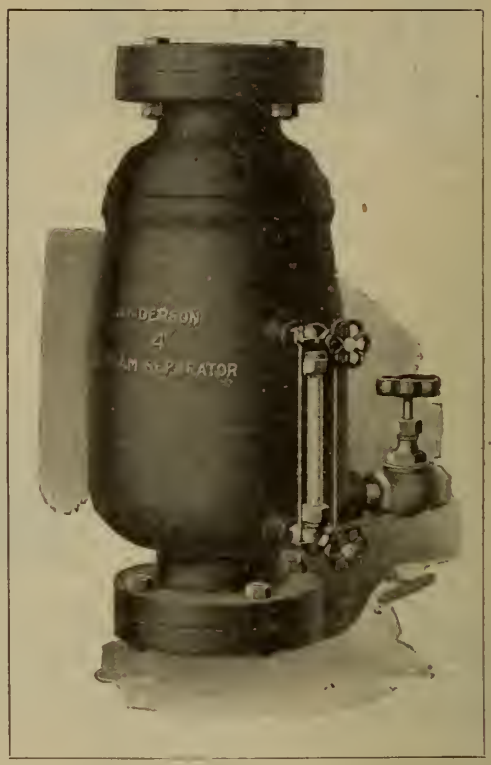
Breakdowns a Thing of the Past!

You can't afford to have any engine breakdowns due to accumulated moisture in engine cylinders and turbine casings these days of high production costs—time and labor are too expensive to stand idle. You can count breakdowns of this nature as a thing of the past in your plant by installing the

Anderson Steam Separator



The "Anderson" delivers DRY STEAM under all operating conditions.

The moisture is completely separated by the combined action of centrifugal force, and the sudden reversal of high velocity steam current. All danger of the moisture passing the throttle is obviated.

The moisture cannot be picked up again when once separated. You'll observe from the illustration, that the whirling motion is obtained by means of the internal helical baffle coil.

Write for the catalogue which describes all the Anderson Power Plant Specialties.

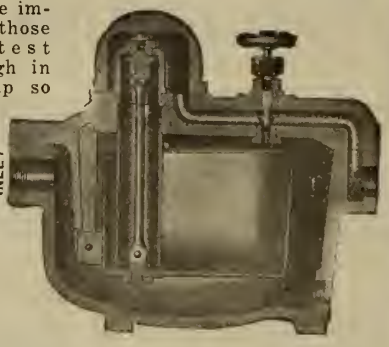
KIELEY

IMPROVED HIGH AND LOW PRESSURE

STEAM TRAP

For General Service

No power plant should be without a dependable steam trap. It is the great economizer of fuel and promoter of power plant efficiency. The KIELEY Improved Trap is the latest development in the art of steam trap construction, and is suitable for all service, either high or low pressure. The important parts and those subjected to greatest wear are placed high in the top of the trap so that by removing two nuts and the small cap all parts are easily accessible and removed for repairs — no breaking of connections necessary, neither do you have to remove the cover. Seats and discs are of best metal, absolutely non-corrosive; for exceptionally severe service seats and discs are constructed of nickel or monel metal, and the bodies of cast iron. Kieley traps never leak when in service—our water seal assures you this.



Leaky, unreliable steam traps are expensive. Adopt the KIELEY and be certain of efficient, economical service.

Top and Bottom Branch Pipes

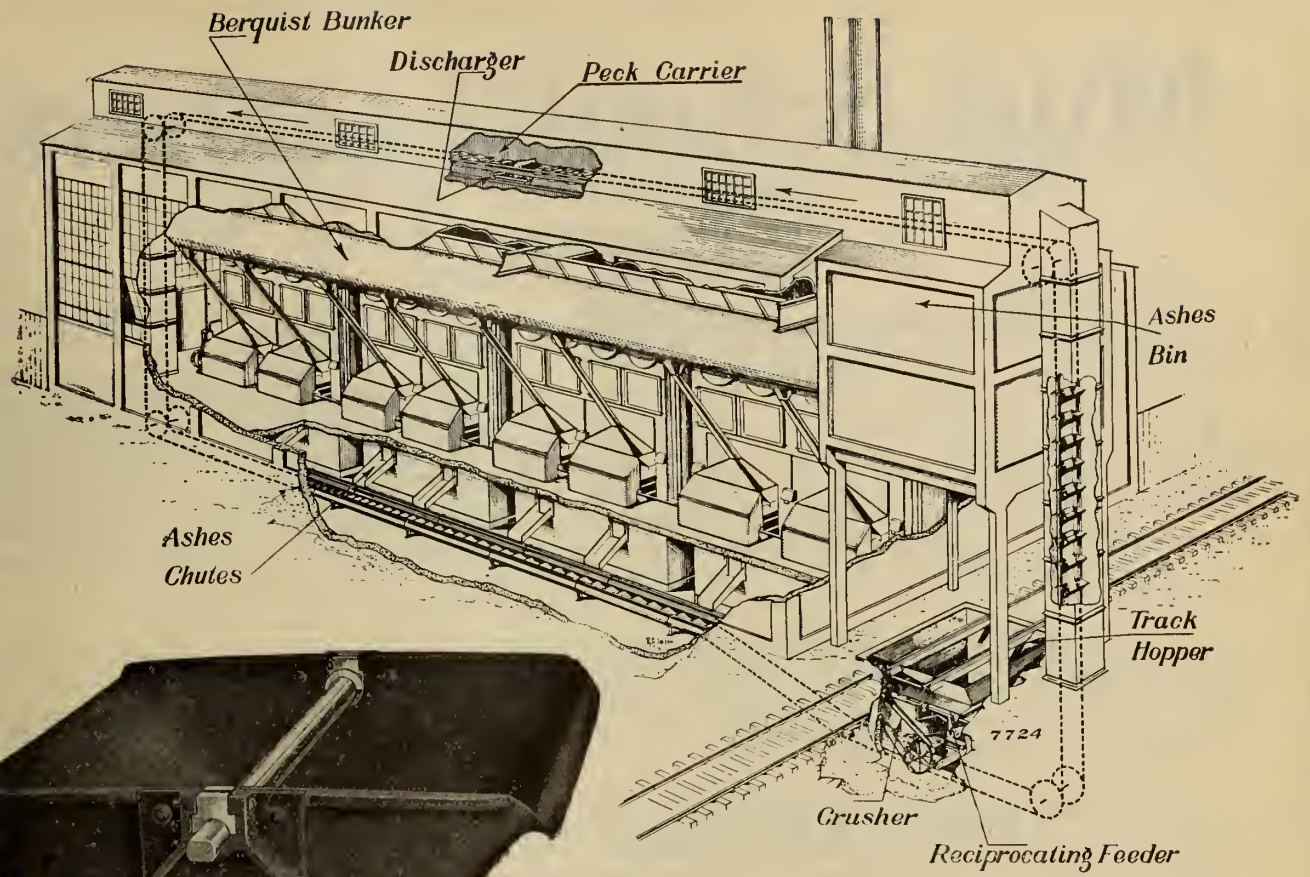
Article No. 5

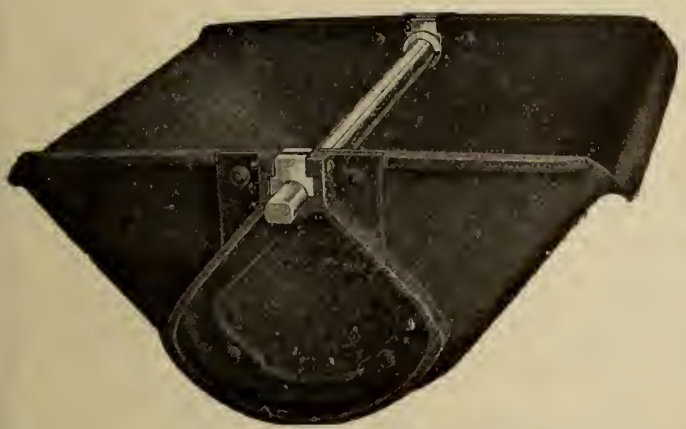
The bottom access branch pipe as shown above connects the bottom headers. The water entering the economiser through this pipe at the end farthest from the boiler, or cold end. Directly opposite each section is a flanged nozzle with lid for inspecting or cleaning the bottom headers.

A blow-off valve is mounted on the bottom branch pipe, through which sludge and sediment may be discharged.

The top branch pipe is similar to the bottom access branch pipe, but cast in one piece with no nozzles for inspection. The hot water leaves the economizer through this pipe at the end nearest the boiler or hot end. The relief valve is mounted at this end of the top branch pipe.

GREEN'S ECONOMISER, LIMITED.
TORONTO





LINK-BELT
Coal Handling Machinery

GRAVITY Bucket Carriers, consisting of a continuous series of buckets pivotally suspended between two endless chains, represent the highest development of the conveying art. As the buckets at all times maintain their carrying position by gravity, a single Carrier can transport material horizontally, vertically and again horizontally, or in any desired path.

The Peck Carrier, Patented, is the highest development of this type of conveyor—in its inherent design, details of construction, and accuracy of workmanship. It is the recognized standard machine for handling coal and ashes in modern power houses, as well as cement clinker, stone, ore and other abrasive materials.

Send for our Peck Carrier Catalog No. 320 and learn why the Peck Carrier is the superior of all conveyors for coal and ashes.

We also design and build elevators and conveyors for handling all kinds of material; coal and ashes handling machinery; coal crushers; chutes; screens; belt conveyors; locomotive cranes; grab buckets; portable loaders; electric hoists; Link-Belt and sprocket wheels; silent chain drives; transmission machinery, etc., etc.

Catalogs sent upon request.

Must School Teachers Starve?

By Sir Robert Falconer, President of the University of Toronto

CANADA is threatened with another epidemic—cheap teachers! A grave warning, showing the seriousness of the situation, has been made public, through the medium of MACLEAN'S MAGAZINE.

The financial attractions in commerce and trade are proving such a lure to the clever Normal School and University graduates that public schools, high schools and universities throughout the Dominion are being driven to engage inferior teachers—if they can get any at all! One teacher in Ontario is paid the princely sum of $300 per annum.

The article gives the opinions on this vital topic of such men as: Sir Robert Falconer; Principal R. Bruce Taylor, of Queen's; Dean of Arts W. Sherwood Fox, of Western University; A. P. S. Glassco, Secretary of McGill; President MacLean, of the University of Manitoba; President Klinck, of Canada's youngest university—British Columbia; President A. Stanley Mackenzie, of Dalhousie; and many others.

"The Thread of Flame"

By Basil King

This famous Canadian novelist has written a remarkable story that deals with a man who loses his identity while fighting in France. This strong novel, "The Thread of Flame," starts in the December issue of MACLEAN'S. This is the first occasion that a novel by Mr. King has appeared in any Canadian periodical prior to book publication.

Other Features of the December Number

"Merrie Gentlemen"—By Arthur Beverley Baxter.
You will think this the best Christmas story since Dickens' "A Christmas Carol."

"Capital and Labor"—By Ralph Connor.
One of a series of articles on "The New Canada and Its Needs."

"Ottawa is Ready for the Worst"—By J. K. Munro.
A humorous and pithy review of events at the Federal seat.

"Better Late Than Never"—By C. W. Stephens.
A bright Christmas story.

"Some Canadian Snobs"—By Montgomery Dix.
A humorous article on some phases of Canadian society.

"A Blighty Christmas"—By Gertrude Arnold.
An article on the way Yuletide was celebrated in a Red Cross Hospital.
And a dozen other articles and stories all of equal interest.

MACLEAN'S will be Twice-A-Month

starting February 1st, next year. An important point to remember. If you want to keep up with things **nationally Canadian,** you'll have to get the MACLEAN'S Twice-A-Month habit.

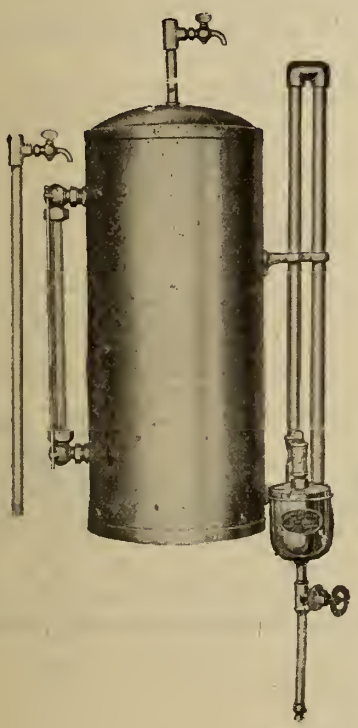
Dollars Going Up In Smoke



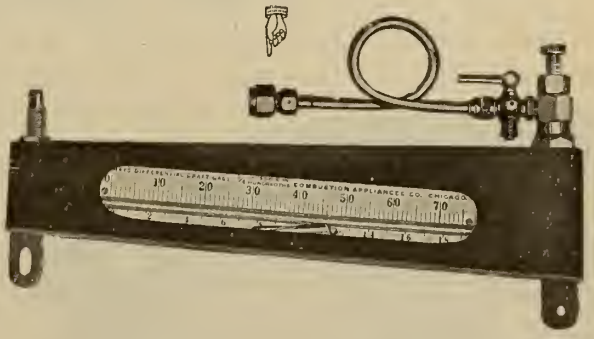
Give the Heat Units to the Boiler

HAYS combustion testing apparatus effects a huge fuel economy. It is a friend of the fireman and a very profitable investment for the plant owner.

It shows at once if draft is proper—if there are holes in the fire—if settings are leaking—if firing periods are improperly timed and other causes of fuel waste.

Gas Collector with water-flow regulator.

The Hays Differential Draft Gage indicates the draft over the fire or the drop in draft through the boiler.



HAYS Automatic CO_2 and Draft Recorders, Automatic Gas Collectors, Draft Gages and other Hays Equipments installed on your boilers keep you posted as to just what conditions your boilers are operating under.

Hays Combustion Efficiency Appliances are leading the way to increased efficiency in boiler firing, a most effective way in offsetting high coal prices.

Ask for our book, **"How to Build up Furnace Efficiency."** It tells how fuel is wasted, how to stop that waste and keep it stopped.

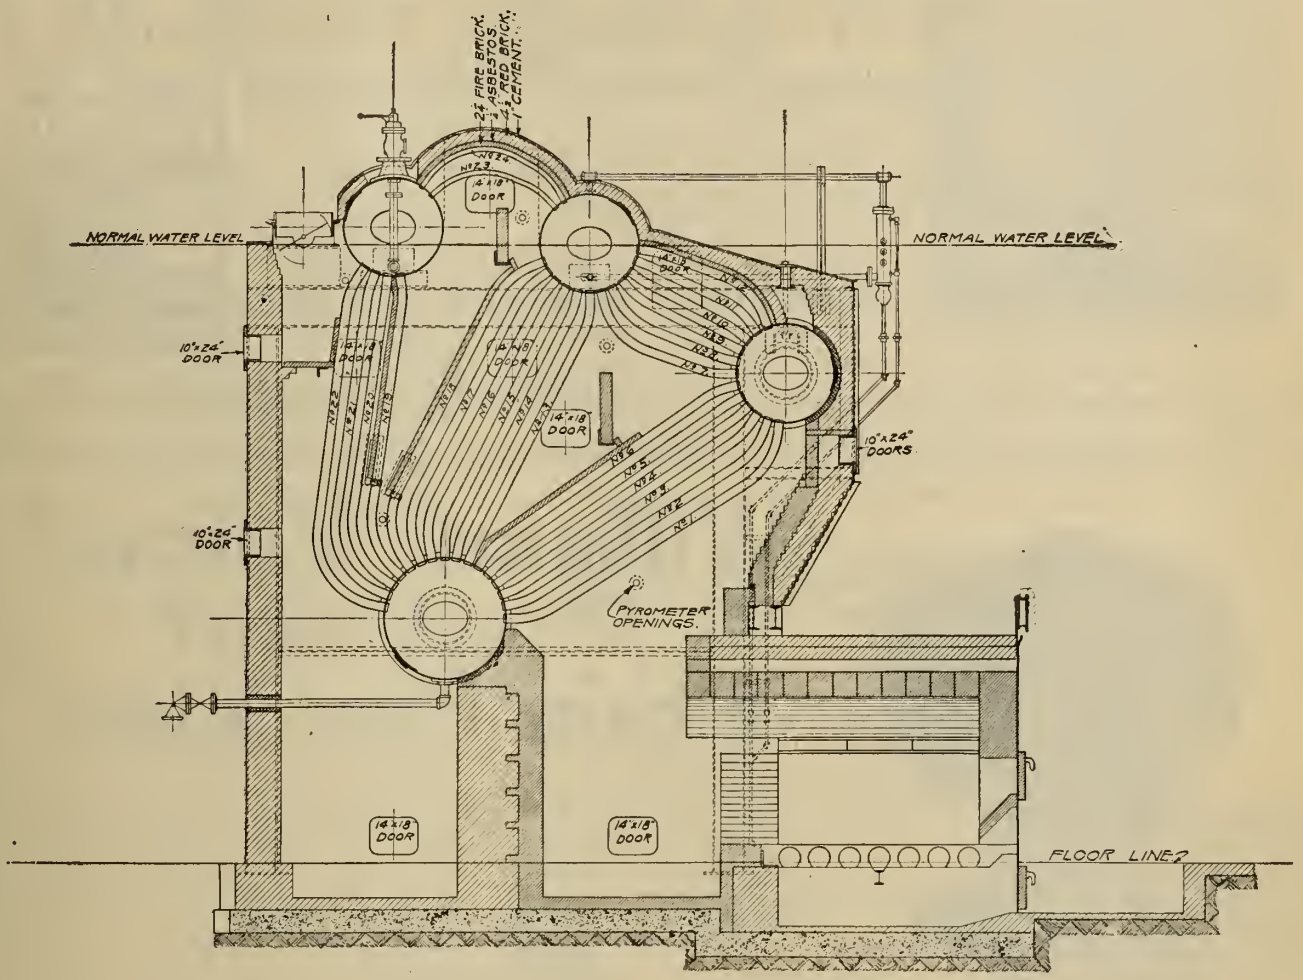
ANY·CAPACITY ANY·PRESSURE



Connelly (Patented) Water Tube Boilers

Made in Canada by

E. LEONARD & SONS, LIMITED

Are of the four drum type and have 100% tube area in the path of circulation which enables them to deliver not only dry, but slightly superheated steam under normal conditions and also when overloaded.

A few of their good points—

Simple in design. Have no flat surfaces. Free from hundreds of joints. No hand holes at end of tubes.

Contain a tremendous volume of water, in proportion to their size. All stress due to expansion and contraction is well taken care of. Boiler tubes are so spaced that any one may be removed without moving the rest.

Designed to get the maximum horsepower in the smallest cubical space.

Can be built in units up to 4,000 horsepower.

Why not Buy the Best, when in market for Packing?

HOLMES'
Metallic Packing
Is Guaranteed 3 Years

Lasts many times longer. 30 days' trial. Less oil. No cutting. Easily applied to any Steam Engine, Air Compressor or Gas Engine. Satisfaction or no pay. Write us.

HOLMES METALLIC PACKING CO.,
Wilkes-Barre, Pa.
Incorporated 1897

McDANIEL IMPROVED STEAM TRAP

FOR HIGH OR LOW PRESSURE.

Steam can't blow through. They have large discharge valves and cannot be flooded from sudden flushes of water.

MAY WE SEND ONE FOR TRIAL?

Reducing Valves, Pump Governors, Relief Valves, Exhaust Pipe Heads, Ejectors and Steam Separators.

SEND FOR CATALOGUE.

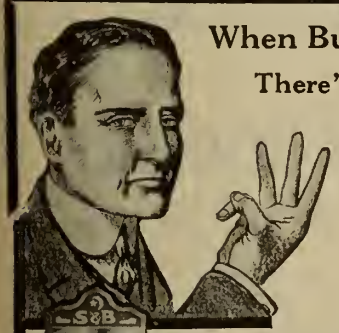
The J. C. Wilson Mfg., Co., Limited

BELLEVILLE, ONTARIO

Mechanical Engineers, Pattern Makers, Founders and Machinists. We build complete Hydraulic Turbine Equipment, Flumes, Head Gates, Racks, Waste Gates and Winches. Water Wheel Governors, Gearing, Pulleys and Shafting.

MAKERS OF THE "LITTLE GIANT" TURBINE

Put Your Water Wheel Proposition Up To Us



When Buying Thermometers

There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—

Second, durability is absolutely essential—

Third, the thermometer must be suitably constructed for the intended application.

Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.

Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application. Also test thermometers, glass thermometers, etc.

Get a copy of Catalog P.H. 200 to-day.

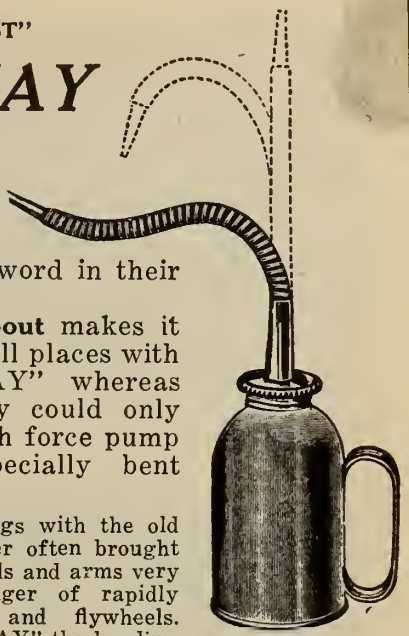
Power Plant thermometers for all temperatures not exceeding 1000° F.

Also—"Columbia" Recording Gauges and Thermometers, Gauges, Gauge Testers, Tachometers, Steam Calorimeters, Counters, etc.

"SAFETY FIRST"

ALL-WAY RAILROAD OILERS



are the latest word in their line.

The **flexible spout** makes it possible to oil all places with one "ALL-WAY" whereas previously they could only be reached with force pump cans with specially bent spouts.

Lubricating bearings with the old straight spout oiler often brought the engineer's hands and arms very close to the danger of rapidly revolving gears and flywheels. With the "ALL-WAY" the bending of the spout removes this danger.

Sizes No. 4, 1 pint—10 in. spout. No. 5, 1 quart—11 in. spout.

Flexible spouts can be furnished for any kind of oiler. If your dealer cannot supply you write us.

We also manufacture the well-known "All-Way" Oil Can—saves you 50% of your oil bill.

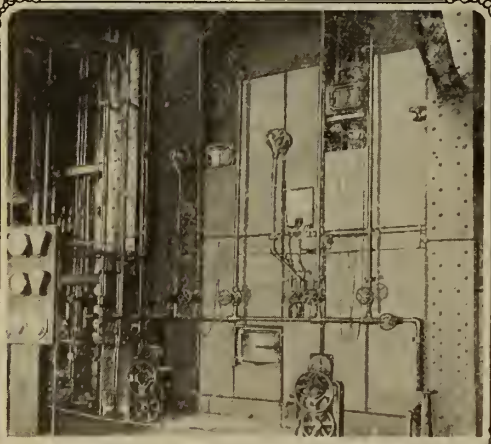
Diamond Soot Blowers on Edgemoor Boilers, plant of Aurora, Elgin & Chicago Ry., Batavia, Ill.



Diamond Soot Blower Installation—Plant of Buffalo General Electric Co.

Standard in the Worlds Largest Power Plants

Visit the boiler rooms of the largest power plants in Canada, and you will find Diamond Soot Blowers in practically all.

Why?

Because Diamonds are essential to the cheap production of power. In no other way, than by their use, can clean heating surfaces be maintained. And clean heating surfaces in a boiler room mean increased ECONOMY, CAPACITY, SAFETY.

You will find Diamond Soot Blowers in the following representative power plants:

Canadian Kodak Company
Canadian Locomotive Company
Canadian Pacific Railway Company
Canadian Electro Products Company
Canadian Pulp & Paper Company
Ford Motor Company
Dominion Forge & Stamping Company
Western Electric Company
British Cordite Company
The Steel Company of Canada, Ltd.
Imperial Tobacco Company of Canada
The Canadian Salt Company
The Beaver Wood Fiber Company
Britannia Smelting & Refining Co.

There are hundreds of others. If the managers, superintendents and chief engineers of these plants consider Diamonds essential, there must be very substantial reasons why your boilers should likewise be equipped.

For full information ask for Bulletin 186

Handle it Mechanically

Every Engineer and Power Plant Manager should have a copy of the new Catalog on the Jeffrey Carrier. Each of its 96 pages contains information of value to the man interested in Coal and Ash Handling Machinery. The JEFFREY Carrier is completely described and important shop views and installations are shown. Blue prints giving all necessary dimensions, clearances, etc., for embodying the Carrier in your Power Plant drawings are included within the covers of this Catalog.

Write TO-DAY for your copy—ask for Catalog No. 210-4.

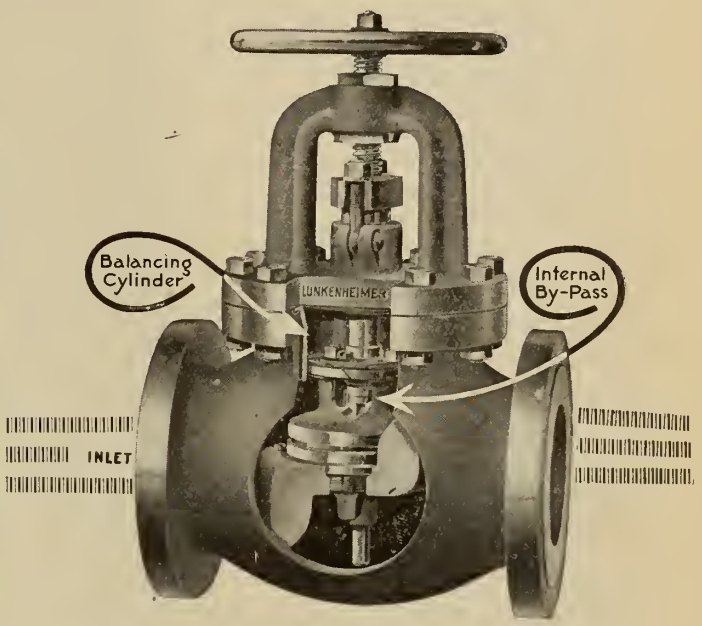
MONTREAL

LUNKENHEIMER

Balanced Throttle Valves



Constructed expressly for throttling reciprocating steam units, they incorporate special features which peculiarly fit them for this service.

The internal by-pass, opened by the first turn of the handwheel, provides ready means for heating the cylinder. It also eliminates wear of the main seating surfaces incident to wire drawing of the steam through a restricted area, and by insuring a gradually increasing flow prevents water hammer.

The main valve disc and seatring have spring seating surfaces which compensate for any distortion that may be caused by expansion or strain. Seating surfaces are regrindable and all parts are renewable.

Globe and Angle Patterns in various material combinations to suit all pressure and temperature conditions. Valves can be connected in either a vertical or horizontal position.

Write for descriptive booklet No. 579-DC.

Lunkenheimer products have long been recognized as the true standard of excellence for quality, efficiency and economy. Their excellent performance under every conceivable working test has proved their dependability. And they are economical because of their durability.

"Lunkenheimer Products" embrace a complete line of Bronze, Iron and Cast Steel Valves, Boiler Mountings, Engine Trimmings, Ground Key Work, Whistles, Injectors and Ejectors, Fittings, Automotive Accessories, etc.

Leading dealers everywhere sell them. Specify LUNKENHEIMER and insist on having the genuine.

Cut Time and Labor Costs

—stop and figure out the time wasted in weighing and computing weights. It amounts to considerable in a year.

Fairbanks Dial Scales

eliminate all the waste time and labor it is possible to save. They put your weighing on an efficient basis. The plainly graduated dial does this.

Ask us about these scales, and the work they will do in your plant.

Scale in Your Boilers

Clean Tubes Mean Coal Saving

And easier firing, less ash-handling, fewer shut-downs, prevention of bagged or burned tubes, fewer repairs, and less frequent wash-outs. METLSKIN can pay for itself in a short time.

is an unprofitable boarder. Its appetite is enormous and it consumes far more than it is worth. Why not give it TWO MONTHS' NOTICE, and put an end to your loss thereafter?

THE SIXTY-DAY TEST OF METLSKIN is open to any reliable concern that is troubled with boiler-scale, pitting or corrosion. A small daily dose of METLSKIN, for a period of two months, will bring down the most tenacious scale, and absolutely convince you that A CLEAN BOILER IS NOT ONLY POSSIBLE, but EASY.

SEND A POSTCARD for the METLSKIN booklet and learn about Our Offer, Guarantee Bond, and Prices.

METLSKIN is neither "Compound" nor "Cure-all."

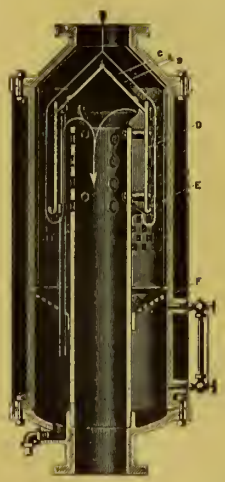
III IMPORTANT THINGS

TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

DURABLA
TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY

Etched on Every Glass

DURABLA HIGH PRESSURE GAUGE GLASS

Detailed tests, which have appeared in previous issues, have proved that DURABLA American made high-pressure gauge glass possesses the elasticity necessary to withstand sudden and radical changes in temperature; that it will remain clear; and that it has unusually high tensile strength.

It now remained to determine what DURABLA U.S.A. glass would do under actual operating conditions. The glass was placed in service in one of the largest power plants in the country on boilers where pressure of 225 pounds is maintained day and night. Under these severe conditions, the service obtained from DURABLA U.S.A. glass equalled in every respect the best service given by any foreign glass ever applied in this plant.

DURABLA U.S.A. gauge glasses are now ready for distribution in all standard sizes and are sold under the DURABLA guarantee.

CANADIAN
FAIRBANKS-MORSE
EVERYTHING MECHANICAL

When the seat of a Pratt & Cady Renewable Seat Gate Valve becomes worn, you can insert new bronze seat rings in a very few minutes. The valve is then as good as new. And the cost is nominal compared with the cost of a new valve.

Anyone with a wrench can easily make this change. There is nothing to become loose or drop out and obstruct the line.

PRATT & CADY
RENEWABLE SEAT GATE VALVES

The gate in these valves is a double-faced, wedged-shaped casting with side grooves, by means of which it slides on guides in the valve body.

Guides in the body are of equal thickness and the wedge can be taken out of the valve and replaced with the opposite faces in contact and give an accurate fit. In making repairs this is important.

These valves being double seated can be used with the pressure applied at either end.

Gauges are used in machining all parts to insure accuracy and interchangeability.

Made of bronze and iron in all sizes. Adapted for steam, air, oil, gas or water service.

Large stock at branches insures prompt service.

May we send you our Catalog?

Advertise for Good-Will

"The last twenty years have witnessed a great development of advertising as a selling force," George Frank Lord, advertising manager of the E. I. du Pont de Nemours & Co., told the Pittsburgh Advertising Club.

"I venture to predict that in the next five years advertising will be recognized chiefly as a great buying force. Instead of using advertising to sell merchandise we will use it to buy customers. For the purchase of good-will it will be classified, even by accountants, not as current expense, but as a long-time investment; a sort of bond that yields dependable interest annually and amortizes itself in ten years, but keeps on returning interest indefinitely.

"If advertisers and advertising men will keep their minds fixed on this idea of buying good-will, or buying satisfied customers, instead of selling merchandise, many of the most difficult problems of advertising will disappear. Appropriations will not be based on last year's earnings, the current year's estimate, the sales department's gross margin, or the tentative impulses of the board of directors, but on clear analyses of the amount and kind of good-will needed for the ideal future of the business, the time required or available to develop it, the total amount it will be worth, and how the expenditure of that total will be made in various years.

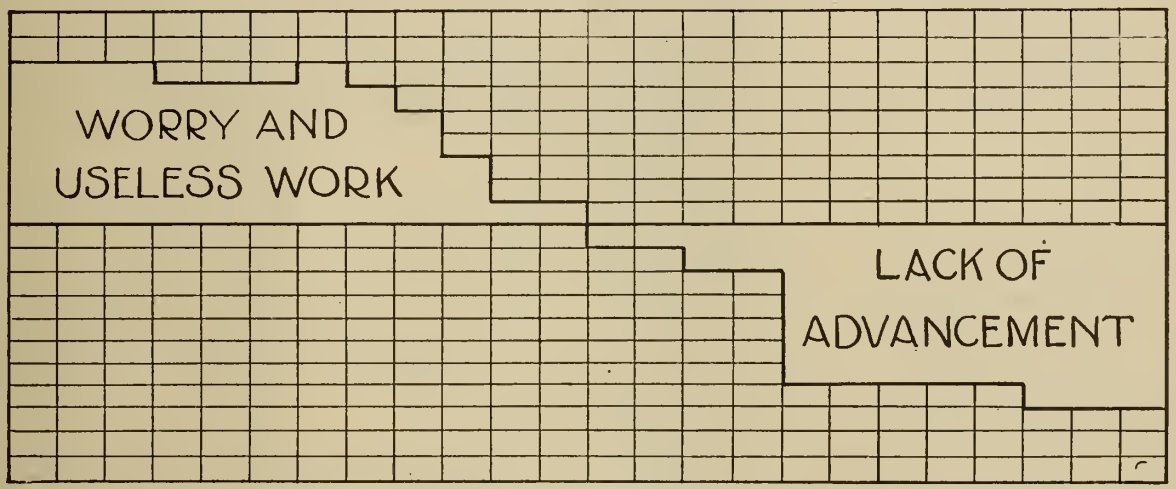
"The advertising policy will not be shifted by the weather, the crops, temporary trading conditions or changes in organization. The business itself will have a definite, enduring policy, and the advertising will express it.

"There will be no lying copy, nor merchandise that is made only to sell, and not to use; because such things do not buy customers and are destructive of good-will, the great asset the advertiser is seeking.

"Whether an advertiser formally adopts the policy of buying good-will or not, the good-will value of his advertising is all he really gets for his money. The advertising that buys satisfied customers adds to his good-will, and that which creates dissatisfied purchasers subtracts from his good-will.

"Success is merely the result of having more plus than minus in the good-will account. Since the whole history of advertising proves this is true, why should we not recognize this truth and consciously get in line with it?"

Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

A half turn on the lock nut makes a solid gage out of this Sheet Metal Micrometer. The ratchet friction feed insures uniform pressure against the work without danger of springing the frame. Like all Starrett Tools, it carries an absolute guarantee of accuracy and quality.

IS THIS THE SOLUTION?

Another scheme to rectify the distressing prices now prevalent, by other than sound economic measures, was outlined before the Union of Canadian Municipalities which recently convened at Kingston.

THIS RESOLUTION HITS YOU WHERE YOU LIVE

"We submit the principal root of the evil is the present wasteful, inefficient and antiquated method, or rather lack of method, of distributing the goods from the producer and manufacturer to the consumer—wasteful of time, labor, health, happiness and even human life—inefficient and antiquated in this age and to such an extent that even the huge economies effected by the greatest array of labor-saving machinery the world has ever seen are in a large measure rendered null and void. An ever-increasing army of unregulated distributors and relatively an ever-decreasing army of producers with the leaders of all these practising profiteering and price-manipulation as their fancy may dictate or opportunity may permit.

"Among the minor causes are the various classes of idlers and usurers, who in devious ways levy toll on labor and industry. Waste of time in high schools and colleges teaching dead languages and other unpractical subjects to the partial or total exclusion of vocational training, economics and useful branches of learning which would be of greater value for purposes of mind development and discipline and thereafter more useful to the individual and the country."

SAYS THE FINANCIAL POST IN REPLY:

"It is, of course, possible that there might be a dissenting voice, heard above this chorus of condemnation. A voice that might suggest, for instance, that the fact that the producer is getting $24.50 per hundred for hogs, where he formerly got $6, might, perhaps, have as much to do with the matter of increased cost as the inefficient handling that gives to the packer 5-16 of a cent per pound on bacon, or to the retailer a bare 5 cents a pound. Or the fact that the farmer is now guaranteed a price of $2.15 a bushel for wheat that formerly he sold with satisfaction for 90 cents, may be as much responsible as the half cent a loaf profit of the baker, or the cent profit of the retailer.

"It is a question, too, whether all the blame for the trying conditions of the present time should be laid at the door of established trade, any more than at any other door. There seems no good evidence for believing that the business morals of the merchant class are worse than any other, and there might be those who might reply to the stricture that our schools and colleges are not devoting their attention strongly enough to the bread and butter needs that "man does not live by bread alone."

The frank object of this resolution was "to attain a substantial reduction in the cost of living generally, but without increase of hours of labor or reduction of wages." It is the possibility of this which THE FINANCIAL POST doubts.

You want to read such discussions as this. They appear weekly in THE FINANCIAL POST.

DEFENDER

DUPLEX DRAFT GAUGE

The Peer of Them All
Price $20.00

They read: Draft over the fire. Draft at the last pass of the Boiler and the differential through the Boiler.

THE FIREMEN CONTROL the fires by the readings on the Gauge. It shows every condition of the Fires and Boilers, except Flue Gas Temperatures and the Defender Flue Gas Pyrometers show the Flue Gas Temperatures. Also see the Defender CO_2 Analysers, put up in permanent case so as to take a reading for CO_2 in less than one minute's time. Write for Bulletin No. 100.

Defender Catalogue No. 11 shows the largest assortment of Combustion appliances, efficiency instruments and damper regulators made. We can help you save fuel.

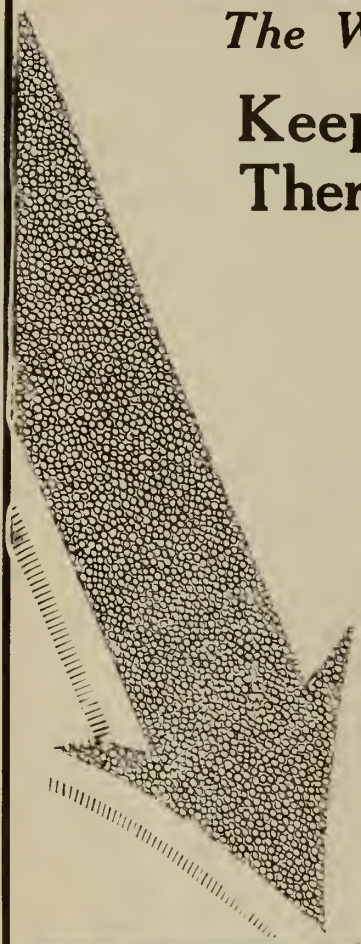
PYRO PUTTY

TRADE MARK REG U S PAT OFF

FIRE BRICK IN PUTTY FORM

The World's Best Furnace Lining Material



Keeps Hot Air In and Cold Air Out Thereby Increasing Furnace Efficiency

Pyro Putty is far more durable than standard fire bricks for making new furnace linings, because it is not weakened by a multiplicity of fire clay joints.

And for repairing worn furnace linings, Pyro Putty will prove ECONOMICAL, because repairs can be made quickly by unskilled labor. Simply pound the material in place with a mallet, smooth it off with a trowel and the job is done.

Pyro Putty is put up ready for use, in 700-pound barrels, a barrel being equivalent to 100 standard fire brick.

The sketch below represents the fire box of a water tube boiler lined with Pyro Putty. Compare it with your own fire box linings; then

Order a few barrels and keep them on hand for emergency repairs.

A few barrels of Pyro Putty should be part of the emergency equipment of every steam power plant.

BEST OF SHAKING GRATES

Nonpareil

Shaking and Dumping Grate Bar

YOU CAN'T BEAT THIS !

Will enable you to produce steam at the minimum possible cost.
REDUCED COAL BILLS **PERFECT COMBUSTION**

If you want to be convinced, ask the Heinz Co., of Leamington — they have several large sets, and are highly pleased.

THIS IS OUR GUARANTEE:

We offer to install a set of our Nonpareil Shaking and Dumping Grate Bars of any size, under any kind of a boiler for a trial period of thirty days, and guarantee to show a saving of not less than 10% of your fuel, guaranteeing our grates to give entire satisfaction in every particular. You will be the sole judge. **If you are not satisfied with the Grates at the end of that period remove them and ship them back to us, we paying all freight charges.**

7450 square feet of Nonpareil Bars installed from Jan. 1st, 1919 to Dec. 18th, 1919.

FOR GRATE BARS and repairs to all shaking grates and boilers of all sizes, see us or write for particulars.

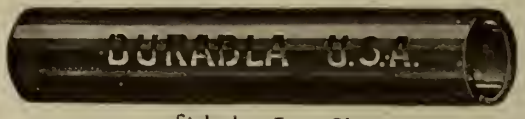
STRENGTH—GOODNESS—QUALITY



Etched on Every Glass

TESTS OF HIGH-PRESSURE GAUGE GLASS

Temperature:	Not affected after 18 two-minute submersions in oil at 380 deg. F., then in water at 40 deg. F.
Erosion:	No trace of erosion, and perfectly clear after live steam at 100 pounds pressure had passed through the glass for 96 hours.
Tensile Strength:	Remained unbroken under hydraulic pressure of over 2,000 pounds per square inch for 2 minutes.
Service:	Under continuous operating conditions with pressure of 225 pounds, performance equaled in every respect the best service ever obtained by any foreign glass.

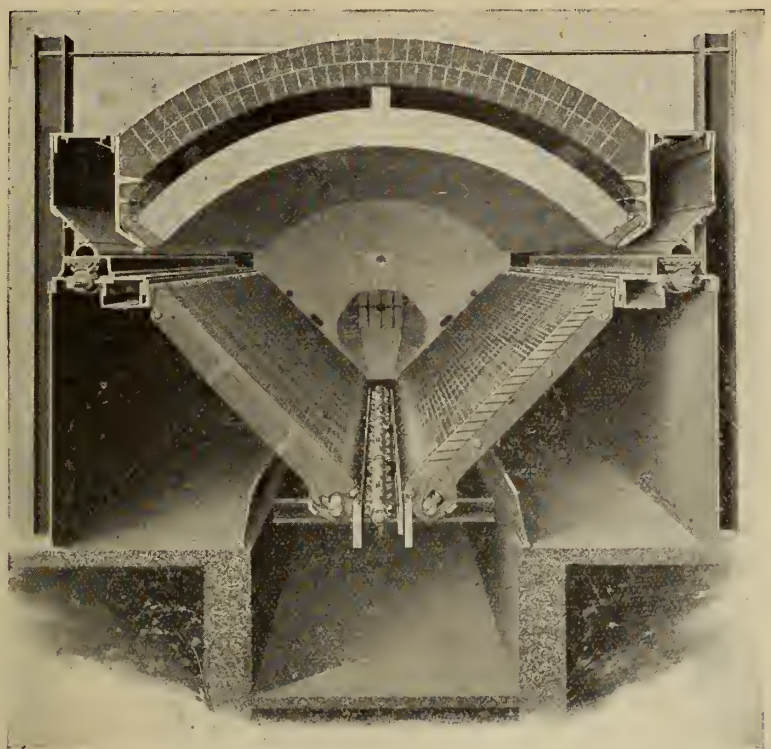
DURABLA U.S.A. gauge glasses are now ready for distribution in all standard sizes and are sold under the DURABLA guarantee.

MADE IN U.S.A.

DURABLA MANUFACTURING CO.

NEW YORK CHICAGO PITTSBURGH PHILADELPHIA DALLAS

DURABLA



Cross section showing the construction and operation of the Murphy Automatic Furnaces. As the fuel progresses downward the alternate movement of the grates ¼" above and ¼" below the surface of the stationary grates breaks up the fuel bed —prevents avalanching—keeps the grates clinker-free and advances the ash gradually to a point where it is removed by the clinker grinder.

Burns Anything

Yes! It burns successfully more different grades of coal than any other furnace ever devised.

MURPHY AUTOMATIC FURNACES

When you can't get bituminous coal you can keep the plant operating on slack—lignite—sawdust or even refuse, if the plant is equipped with Murphy Automatic Furnaces.

Why not send for catalog HM-12 and see what Murphy Furnaces are doing in plants right in your vicinity.

For information on the Riley Underfeed Stoker for large boiler see advertisement in last issue or send for catalog HR-12.

Murphy Iron Works

Detroit, Mich., U.S.A.

BURN ANY FUEL THAT HAS HEAT IN IT

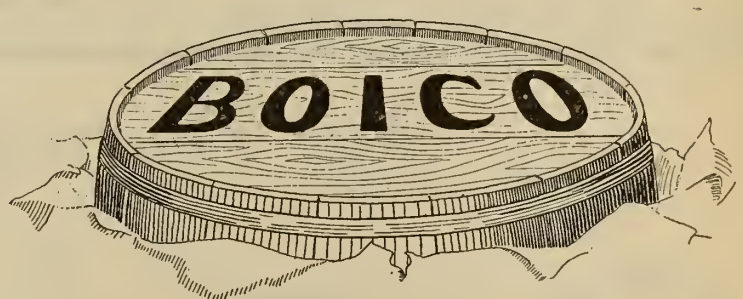
The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost.. You have nothing to lose by trying it—let us hear from you.



Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Shell-Bar Boico Supply, Limited 376 Dufferin Street Toronto

Eastern Sales Agents: Mill Supply Department, Beveridge Paper Co., Ltd, Montreal; Adolphe Huot Reg'd., Quebec

Scrapers Article No. 6

Soot is kept from collecting on the exterior of the tubes by self-aligning scrapers which travel continuously up and down the tubes at a slow speed.

Each scraper as shown is composed of three parts with beveled cutting edge top and bottom. Both edges are directed upward and the three parts of the scraper are so supported that on the up stroke they are forced against the tube, thus scraping the tube very clean. The soot falls between the ovoid bottom headers into the soot pit.

The scarfed joint between the parts of the scrapers insures that the whole tube is cleaned and no ridges of soot left on the tubes. A clearance is left on this joint, allowing gradual wearing of the cutting edges without the parts binding. The extra heavy construction and ample length of the scrapers result in strength, long life, steadiness and freedom from sticking.

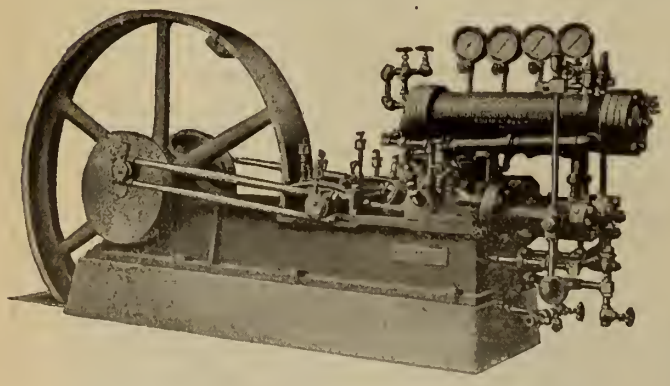
NORWALK
AIR & GAS · COMPRESSORS

For Thoroughness



A Norwalk Four-Stage Belt-Driven Air Compressor

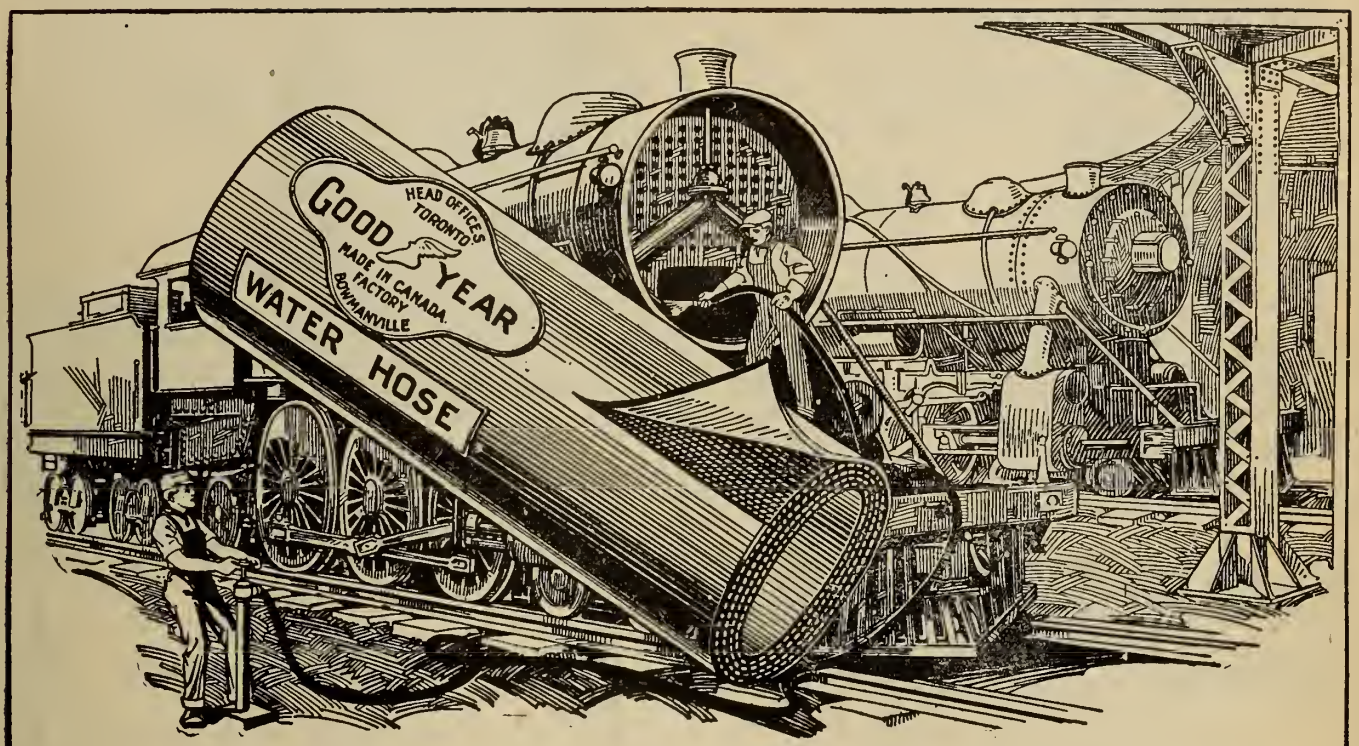
NO Norwalk Compressor goes out until we are satisfied through rigid tests that it will give the buyer year-in and year-out satisfaction.

Norwalk thoroughness is based upon the conviction that **no detail** is too small to receive the best attention of experts—or too small to be 100% right.

There is a bulletin for each branch —Air, Oxygen, Hydrogen, Acetylene and Carbonic Acid Gas. One or all sent upon request.

THE NORWALK IRON WORKS COMPANY
Pioneer Builders of Compressors
South Norwalk, Conn.

ANY·CAPACITY ANY·PRESSURE



This Cover Reduces Costs *on Industrial Water Hose*

We never heard of industrial water hose bursting because of internal pressure. Any fairly good water hose will stand all the pressure it will ever get in industrial use.

But we have seen and heard of thousands of feet of water hose which had to be discarded long before its time because the *cover* wore through.

That fact guided Goodyear scientists in designing Goodyear Water Hose.

They started with a good inner tube and strong fabric.

But they put on this hose an unusually thick cover of exceptionally tough rubber.

Water Hose is dragged over floors and pavements and steel plates. It is walked on and run over by hand-trucks and wheelbarrows. It is left outside rain or shine. *The Goodyear cover on Goodyear Water Hose is built to stand this use.*

That is why Goodyear Water Hose wears longer and so costs less.

That is an example of the way Goodyear builds all Industrial Hose—

—finding out what conditions must be met, and then developing the materials and construction to meet them.

Goodyear has scientifically developed a hose for every industrial use. Samples of this hose, and the advice of a trained technical man, are yours for the asking—without obligation. Phone, wire or write the nearest branch.

Greater Power at Smaller Cost

REDUCE the friction load in your plant and get maximum power from every ton of fuel. Reduced friction also lengthens the life of machinery and adds to profit by reducing repairs and replacements and by a greater continuity of production.

Bigger and more dependable output from power-generating and power-using machinery is largely a matter of lubrication—*correct* lubrication, and *correct lubrication means good lubricants and the right one for each lubrication need.* Even lubricants of highest quality, like Imperial Lubricants, will not give the desired results unless they are properly applied.

Imperial Lubricants are right. They are carefully formulated from the best crudes. There is the *right* lubricant for the correct lubrication of every part and every machine under every service condition.

There are none better at any price. The use of Imperial Lubricants will make and keep your machinery efficient and capable of delivering maximum power at least cost per h. p. hour.

Consultation with Imperial Lubrication Engineers is yours for the asking. They will gladly study your lubrication problems and submit recommendations. Write to 56 Church Street, Toronto, or any of our branches.

BRANCHES IN ALL CITIES

Burn Low Grade Coal CUT FUEL COSTS Burn Refuse

This winter high-grade coal promises to be scarcer than ever, thus higher priced. Many power plants will have to substitute low-grade fuel and to many this will mean the installation of extra boilers to supply the required steam.

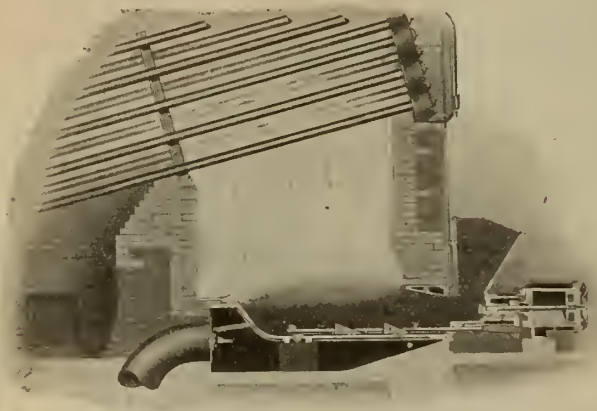
"Jones Underfeed Stokers" will burn low-grade fuel, keeping up your steam pressure and meeting your peak loads without installing extra boilers.

We furnish special stokers to burn Lignite

SMOKE ABATEMENT

The "Jones Stoker" assures proper combustion of fuel which means that the stack will be free from smoke.

The Jones simple construction means durability, no parts move in contact with the fire—no grates to burn out—no sifting of fine coal to the ash pit.



A Jones Underfeed Stoker setting under Water Tube Boiler.

The Jones Underfeed Automatic Stoker

pioneered and developed commercially the Underfeed principle of firing, which is to-day recognized as the most efficient method of stoking.

FACTS AND FIGURES ON REQUEST.

Jones Underfeed Stoker Co.

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.

"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

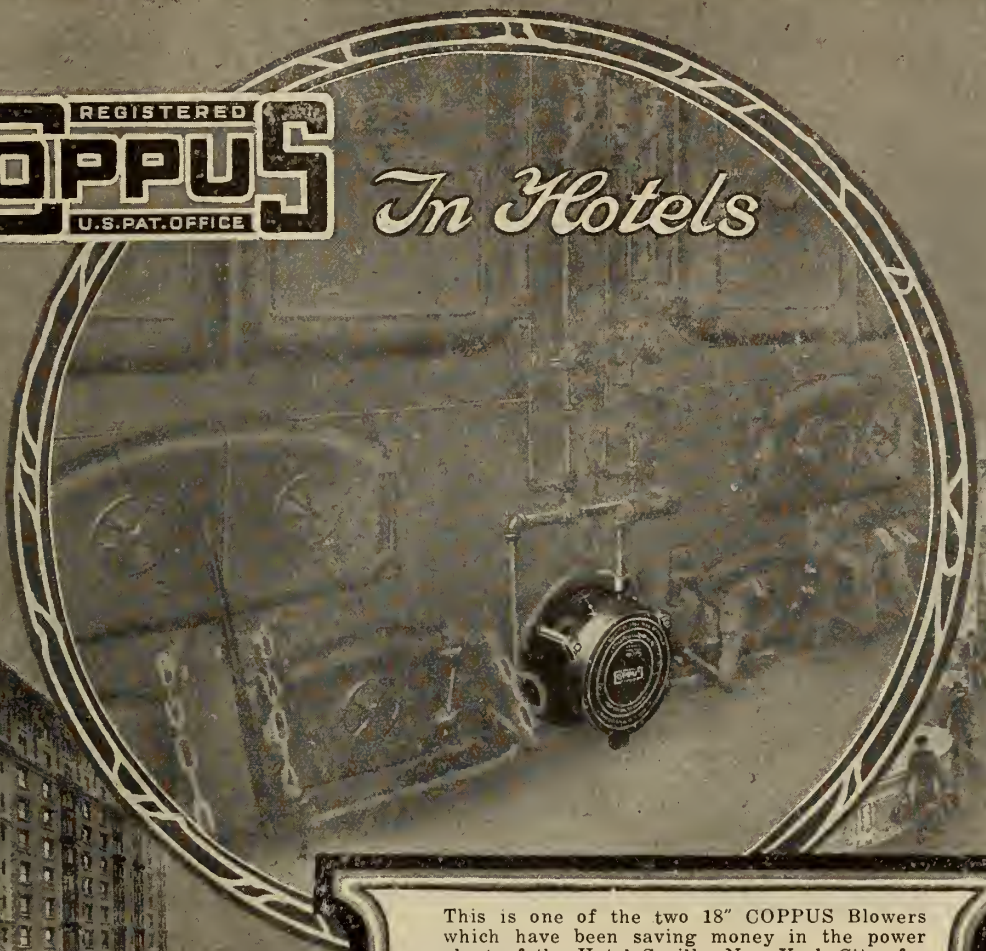
Write us for prices, and if desired we will be pleased to furnish samples and further information.

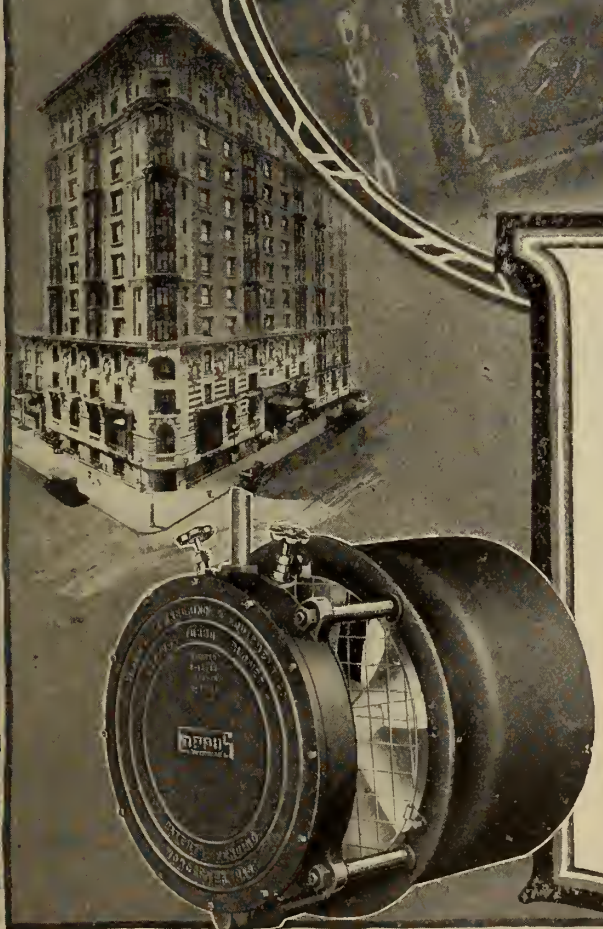
A trial order will convince you of their utility.

DOMINION BELTING CO. Ltd., Hamilton, Canada-Quebec Branch: 51 Duluth Bldg., Montreal

REGISTERED COPPUS U.S.PAT.OFFICE

In Hotels





This is one of the two 18" COPPUS Blowers which have been saving money in the power plant of the Hotel Seville, New York City, for more than two years. They cut coal costs, meet peak loads quickly, keep steam pressure constant, save firemen's labor, prevent clinkering, get all the heat out of the fuel, and—an important item, run smoothly and quietly without trouble.

That COPPUS Blowers operate as effectively in hotels as in power plants of mines, mills, factories — in power plants of any sort — is emphatically proved by the fact that numerous other prominent New York hotels use blowers bearing our trade-mark. For example, Broadway, Central, Girard, Latham, Marseilles, Martinique, Shelburn, Langham, Theresa, Waldorf Astoria, etc., have satisfactorily demonstrated the money saving possibilities of COPPUS equipment.

What COPPUS Blowers have done in other plants they can do in yours. Allow our engineers to show you how **"COPPUS equipment can save you money."** Write for Blower Catalog H-21.

CLINTON CEMENT

Did You Ever See Two Postage Stamps Stuck Back to Back?

Well, that's the way two bricks stick together when our cement is used.

The greatest loss in your furnace efficiency occurs as the result of leakage, cold air pouring in and interfering with proper combustion.

We Have Got This Licked!

Fireclay dries up and sifts out from between the bricks like powder.

But our cement sets and makes a surface like glass yet allowing for expansion and contraction. It sets hot or cold and stands a heat up to 3,000 degrees Fahrenheit.

This cement makes a joint that is stronger than the bricks themselves, and that is itself the strongest part of the whole furnace.

A five-pound tin of **Clinton Super-Heat Cement** will be sent to you free and all charges prepaid, if you write the

POWER HOUSE

Established 1907 Published Semi-monthly

The Waterpowers of British Columbia—I

The Report by the Commission of Conservation on the "Waterpowers of British Columbia" Contains Much Data of Interest. The Following Article, Published Through the Courtesy of the Commission, Presents a Summary of a Portion of the Report

IN January, 1910, the Commission of Conservation commenced the investigation of the character and extent of the various natural resources of Canada. Early in 1909 the Canadian delegation to the North American conference at Washington had compiled a general statement respecting the available water-power data. This compilation served to demonstrate the inadequacy of the information respecting this valuable natural resource. The commission, therefore, decided to prepare an inventory of the water power resources of the country, and, in so doing, avoided duplication of effort by utilizing all available information from governmental and other sources.

The commission commenced its own reconnaisance field work in the eastern provinces, and, in 1911, published "Water Powers of Canada," which represents, in summary form, the information then available for the provinces of Prince Edward Island, Nova Scotia, New Brunswick, Quebec and Ontario. Owing to the paucity of information available, it was not then possible to do more than describe briefly the water-power resources of the provinces of Manitoba, Saskatchewan, Alberta and British Columbia.

The conditions affecting powers in the province are unique, and do not closely correspond to those existent in other portions of Canada. This is especially true of the mainland Pacific coast. One cannot but be impresesd with the fact that coastal water-powers in British Columbia, which, to the casual observer, appear to be of comparatively small amount, nevertheless, may, when economically and fully developed, yield several-fold the estimate of power if appraised upon the same basis as similar streams in Eastern Canada. Glaciers, snowfields, and heavy rainfall abound, and, with many storage possibilities, constitute unique factors which contribute to enhance the values of powers. These conditons, on the other hand emphasize then ecessity of special and very careful engineering investigation and expert handling.

Total Estimated Horsepower

Grand totals purporting to represent horsepower possibilities for large sections of a country are apt to be very misleading. They are especially misleading when used to make comparisons with other totals, when, as a matter of fact, no real basis for comparison has been established. The unique character of many of the water-power possibilities of British Columbia with its exceptional physical features, such as mountain systems, glaciers, snow-fields, and widely variant precipitation, necessarily makes it difficult to effect comparisons between the total water-power possibilities of this province and those of other areas differing markedly in physical characteristics. However, it will be interesting to present in round numbers certain totals of horse-power derivable from the various estimates presented in the tables which form part of the report.

Conventionally, the province has been divided into districts, as follows:

	24-hour horse-power.
I. Columbia River and tributaries (north of the international boundary): This comprises the portion of the province lying between its eastern boundary and the watershed of the Fraser River	610,000
II. Fraser River and tributaries: This	

AKOLKOLEX RIVER, TRIBUTARY TO COLUMBIA BELOW REVELSTOKE. OVER 300 FT. FALL IN SHORT DISTANCE.

includes practically the entire area of the great interior plateau	740,000
III. Vancouver Island	270,000
IV. Mainland Pacific Coast and adjacent islands (except Vancouver Island): This includes all the rivers north of the Fraser which drain into the Pacific	630,000
V. Mackenzie River tributaries (a rough estimate made for inclusion in this summary)	250,000
Grand total	2,500,000

The above totals include about 250,000 horse-power for plants already in operation, but they do not include about 400,000 horse-power given in the tables for power possibilities on streams like the Fraser, Thompson, Skeena and Nass rivers, on which, because of the proximity of railways, or possible interference with the salmon industry, economical development, cannot be considered under present conditions. Also, as elsewhere explained, there is still considerable territory, especially in the more northerly portion of the province, which it has not been possible to investigate fully. These areas may yet disclose a considerable amount of power. One fact to be borne in mind in conection with these totals is that, when powers are developed and the available waters are intelligently conserved, more power will be obtained than the quantities estimated upon the basis of available data would, at present, indicate.

In round figures, the total estimated 24-hour power, including an allowance for all of the entities above mentioned, may be placed at about 3,000,000 horse-power.

Water as a Natural Resource.

Water-power development is but one of the important uses to which many of our inland waters may be applied. Too frequently, in reports on water-power resources, it has been the tendency to deal with power development exclusively, without adequately considering such related subjects as domestic and municipal supply, agriculture and irrigation, navigation, fisheries and riparian rights.

Precipitation, in the form of rain or snow, virtually constitute the only source of inland water supply. Its distribution and efficient use are largely determined by the natural or cultivated properties of the ground on which it falls. Of the total precipitation on the earth, speaking very generally, about onehalf is evaporated; about one-third is "run-off," that is, it runs off over or through the ground, and, by means of the various watercourses, eventually reaches the sea; about one-sixth is taken up into plant structure or otherwise absorbed in process incident to growth. What is known as the "ground-water" serves as a balancing reservoir, being drawn upon during periods of rapid plant growth or of deficient precipitation, and being replenished during seasons of plentiful supply.

The proportion of the precipitation which runs off is that which provides the water for power development, but it must be recognized this same water may also be required to furnish a supply for domestic and municipal purposes, for irrigation, for industrial and manufacturing purposes, or for navigation and fisheries.

Many interdependent and interrelated interests are primarily dependent upon water, and, consequently, keen discrimination is necessary in determining what importance shall be attached to the development of any particular water-power. The subject of power development must be treated with due consideration for the other uses for which water may be required; therefore, in the following paragraphs, water is viewed broadly as a natural resource, and the claims of other interests upon this resource, are discussed.

Run-Off and Forests.

Much has been written respecting the influences of forest cover upon precipitation and run-off. Some of the views expressed differ greatly, due chiefly to the fact that the authors have occupied almost entirely different viewpoints, and these they have not sufficiently defined. We shall refer here to only one or two aspects of the subject.

Irrespective of whatever opinion may be held as to the effect of forests in influencing the amount of precipitation, it is conceded that no topographic feature, generally speaking, ministers more efficiently to gradual and economical run-off than do areas covered by vegetable growth, whether it be forest or such other growth as will correspondingly regulate or temper the run-off. Thus it is that failure to intelligently conserve forest areas has caused great destruction of forest floors and agricultural lands. The damage occasioned by repeated forest fires, especially if the ground is rocky and the soil cover scanty, is exceedingly bad, and contributes greatly to excesive flood run-off. The annual destruction of property by floods appears to increase rather than diminish.

ELK RIVER CANON FALLS FROM DEWDNEY TRAIL BRIDGE, ELKO, B.C.

Serious floods frequently occur as a result of a heavy snowfall upon ground which has been frozen after having first been saturated with water. When this snow melts it is very apt to augment, materially, the surface run-off, because the already frozen ground precludes the usual absorption.

Occasionally, forests may even accentuate floods. When, for example, the winter's snow is retained by a forested area until late in the spring, and then a marked rise in temperature or warm rain occurs, the real net effect of the forest cover would be to accentuate flood stages. Of course, such factors as the character of the forest floor, its porosity and depth, the nature and permeability

of the sub-soil, and others, all exert their influence.

In the case of water-power development, therefore, it is necessary to determine whether the advantages accruing from the industries which propose to use the water-powers wil be more than counter-balanced by the disadvantages resulting therefrom. Thus, for example, wood-pulp mills, if their operation might result in practically denuding the land of forest growth, had beter not be established at all; or, if established, they then should be operated under the strictest regulation and supervision, designed to perpetuate the forest growth. A deforested, eroded and scoured territory, which has lost the humus of its soil, cannot hold the beneficent rains which, instead of being retained in the ground and transmuted into plants by the various processes of growth, carry destruction in the pathways of their torrential run-off. The water is necessary to the soil, and the soil, with its plant growth, is necessary to an economical disposition of the water.

Water Power and Agriculture.

Consider, next, a little more in detail, the possible effects which the depletion of underground water by diversion for power or other purpose may have upon agriculture. Underground waters are by no means inexhaustible.

Underneath the surface of the earth is a vast body of water which may be likened to an underground lake, called the ground-water. It has been estimated—again speaking generally—that the moisture in the upper 100 feet of the ground is equivalent to a lake of water some 17 feet deep, i.e., the equivalent of about seven years' rainfall. It is into the upper surface, termed the water-table, of this ground-water that wells are sunk for domestic and other water supply. During periods of plant growth this ground-water yields, chiefly by capillary action, part of its moisture to the plants; and then during seasons of excessive rainfall is again replenished. Under normal conditions, the annual fluctuation in level of the water-table is but a few inches. Such states as Minnesota, Iowa, Wisconsin, Southern Michigan and the Dakotas have, it is stated, already experienced alarming and permanent recedence in the levels of their ground-waters, and a consequent diminution in crop production. Large sums of money have been expended by the federal and state governments in the United States, on the investigation of the occurrence and flow of underground waters, should be considered together, more recognized that proposed disposition of the run-off, and underground waters, should be considered together, because of a natural balance that exists between them.

It is easily possible to so divert some channels or water-courses as to allow much of the ground-water to be lost, and consequently cause permanent damage to a large expanse of territory. Great waste and carelessness have been manifested in many localities by the users of the underground waters. In the smaller towns, more especially in the east, where the domestic wells furnish so much of the water supply, it has frequently been observed that when some deep trench, as, for example a cut for a new sewer or a mine shaft, has been excavated, the underground waters have drained away, thus "bleeding" the adjacent territory and causing wells of the neighborhood to go dry. The lessons that may be drawn from such illustrations should not be forgotten in considering our valuable underground waters, when viewed locally or with respect to their provincial or larger areas.

Of this ground-water, the late Dr. W. J. McGee, secretary of the United States Inland Waterways Commission, and expert in charge of soil water investigations of the United States Department of Agriculture, states:

"It is the essential basis of agriculture and most other industries, and the chief natural resource of the country; it sustains forests and all other crops, and supplies the perennial streams and springs and wells used by four-fifths of our population and nearly all of our domestic animals. Its quantity is diminished by the increased run-off to reforestation and injudicious farming. Throughout the upland portions of the eastern United States, the average water-table has been lowered 10 to 40 feet so that fully three-fourths of the springs and shallower wells have failed, and many brooks have run dry, while the risk of crop loss by draught has proportionately increased, and the waste through the Mississippi has increased over 15 per cent."

In connection with his work for the Department of Agriculture, Dr. McGee assembled the records of some 35000 wells scattered throughout the United States, and as a result of his research has made the following statement:

"Second in order, but first in significance, among the results of the inquiry is a clear quantitative indication that the subsoil-water level is, and has been since the settlement of the country, lowering at a considerable rate. The rate of change varies from region to region and state to state, ranging from a slight rise in irrigated districts to a lowering of about 3.5 feet per decade. In the 31 states forming the half of the country best adapted by natural conditions to feeding and clothing a great people, the average lowering since settlement would appear to be no less than 9 feet, i.e., from well within, to about the limit of capillary reach from the surface. The data, indeed, indicate that lowering generally was more rapid within the first generation after settlement than later, yet the figures used in the estimates are derived from the reduced rate of the last two decades rather than the more rapid lowering of earlier decades. It would appear also that the actual loss of water attending the lowering is 10 per cent. of the aggregate volume within the first hundred feet from the surface — a national loss of substance comparable with the destruction of forests and the uses and

ICE RIVER GLACIERS TRIBUTARY TO HORNTHKO RIVER. THE FOOT OF THIS GLACIER IS ONLY BETWEEN 300 AND 400 FEET ABOVE SEA LEVEL.

waste of petroleum and natural gas, and far exceeding the consumption and waste of coal and metal. In the light of the relation of subsoil water to productivity, its rate of lowering can only be regarded as a measure of advancing national impoverishment."

In the face of such facts the claims which the ground-water supply has upon its proportion of the rain-fall cannot be ignored. Certainly, watercourses and the sources of their supply should not be so disturbed as to cause a serious permanent depletion, or pollution, of the underground waters. Upon this point, therefore, it is necessary that the amounts, movements, and functions of the ground-water in any district be studied in connection with any general scheme devised for the utilization of water in that particular territory. It must be evident, therfore, that efforts to have the underground waters properly and efficiently used, deserve the fullest support.

STORAGE IN GLACIERS. FROM A SHOULDER OF MOUNT MOLOCK LOOKING SOUTH. NOTE THE WELL-FORMED MEDIAL MORAINE.

The underground waters of Canada, in some places, are now being tapped, and, not infrequently, wasted. In the United States, many states have enacted laws designed to conserve such waters. A main feature of such laws has been the regulation of the flow by actually limiting the size of the pipe through which ordinary domestic and farm water supply may be taken. Sometimes the law states that the supply shall be taken through a half-inch pipe, which shall be furnished with a stop valve. In some state the penalties for violation of the law relating to underground water are severe; for example, in South Dakota:

"If any person complains that the proprietor of an artesian well, or the party controlling such well, is in the habit of letting the waters go to waste, the township supervisor, county commissioner, road overseer, alderman, or other city officers, may enter upon the premises where the well is located in order to determine whether the complaint is justified, and may institute criminal prosecution in case violation of the law is ascertained. If the well is without valves to regulate the flow and prevent waste, the person owning the well may be fined up to one hundred dollars, or be imprisoned not more than three months in jail, or both."

Laws regulating the use of underground waters are needed in Canada. At present, farmers and others are tapping these underground waters and, in some cases where "gushers" have been struck, the valuable waters are permitted to run to waste continuously. This should not be allowed.

Navigable Inland Waters of British Columbia.

In British Columbia there are numerous lakes and many stretches of river which are navigable. By a navigable stream is here meant one which can be navigated by the ordinary flat-bottomed river boat, generally a stern-wheeler. On many of the lakes, steamers of larger size can be used, whilst some swift-flowing rivers, not navigable by stern-wheelers, may be ascended by fast motor craft of shallow draught. There are stretches, not at present navigable, which may be made so by the construction of suitable works. The erection of dams and other works for power development will, at a number of places, improve the rivers for navigation, both by drowning out rapids and by increasing the depths at shallow places. Lockage provisions in all dams should, of course, be fully safeguarded.

Water Power and Fisheries.

Serious consequences to the fishing resources result from obstructions which prevent the free passage of salmon and other fish. This subject is vital in its bearing upon power development, and yet it is frequently passed over.

Practically all of the Pacific Coast streams of British Columbia and their tributaries are annually frequented by vast numbers of Pacific salmon, consequently the salmon fishing industry is one of the most important interests to be safeguarded in the carrying out of works which will materially affect the inland waterways.

There are two main features to the problem of safeguarding the fishing interests in connection with power development: First, to permit a sufficient number of adult salmon satisfactorily to pass all obstructions in order to reach and deposit their own ova upon the spawning beds of the streams; and second, to ensure that the young salmon are afforded a satisfactory passageway out to the sea.

In Canada both federal and provincial legislation has been enacted to safeguard the inland fisheries and to provide for the construction of fishways. The chief difficulty, however, as far as fishways are concerned, is that too frequently proper fishways are not provided, and that such as are provided are allowed to fall into disuse. The Dominion Fisheries Act explicitly provides that fishways shall be built wherever the Minister of Marine and Fisheries determines they are necessary.

Water-power development may also conflict with fishing interests by the destruction of spawning grounds through the manipulation of the levels of lakes used as storage reservoirs. When lake levels are raised the margin of the lake, up to the proposed flowage line, should be stripped of tree growth and underbrush, to facilitate the formation of new beaches and maintain the healthy condition of the water. Here, again, the question of clearing becomes one of weighing advantages and disadvantages, but it is doubtful if any of the supposed advantages derivable from power development will offset the destruction of the source of one of our important supplies of food. Certainly, with intelligent regulation and foreeful administration, the streams of the province should not only continue to produce vast numbers of salmon, but the supply may be greatly increased.

Inland Waters and Mining.

The British Columbia laws relating to water clearly reflect the marked influence which the mining industry has exerted upon the use of water in the province. Mining, in point of value of annual production, has long been British Columbia's most important industry.

although, during recent years, its forest products have sometimes exceeded its mineral production.

Water and water-power have played a most important part in mining development. Without such power as is supplied by the West Kootenay Power and Light Co. the great mining development which has taken place in the southern portion of the province would have been impossible. Large plants have also been established on the Pacific Coast, such as those of the Britannia Mining and Smelting Co. at Howe Sound, and of the Granby Consolidated Smelting and Power Co. at Conservatory Inlet. There are also other, though smaller, hydro-electric plants situated at various mining centres throughout the province, such as those of the Hedley Gold Mining Co. on the Similkameen river, which are contributing materially to the advancement of mining operations. It is interesting to note that the hydro-electric plant of the Canadian Collieries, on the Puntledge river, V. I., has been erected practically at the pit mouth of British Columbia's largest coal mines, thus indicating that hydro-electric power has here successfully competed with cheap fuel. In the future, doubtless, the greatest advances in mining in British Columbia will be dependent upon there being available ample water-power or hydro-electric energy, and probably, many of the smaller and less accessible undeveloped water-powers will be most profitably utilized in connection with mining operations.

In Eastern Canada, as well as in Eastern United States, industries dependent upon electric energy for refining metals are realizing that, before long, they may require to remove to localities where cheap power is available. In the more settled portions of the country, power is no longer obtainable at low rates, inasmuch as it is now required for municipal, domestic, and light manufacturing purposes, which yield a much larger return.

Resume and Summary.

We have observed that precipitation is the prime source of inland water supply, and that not only water-power, but such other interests as domestic and municipal water supply, agriculture, irrigation, navigation, fisheries, mining and riparian rights, are all dependent upon the same source. Consequently, water should not be allotted for power development without due recognition to the just demands of other interests having claims upon our inland waters viewed broadly as a natural resource.

Run-off, manifested in the form of stream flow, is intimately associated with the character of the ground upon which precipitation falls and consequently, care should be taken to conserve vegetable cover; more especially is this necessary for rocky areas which have but scanty soil covering.

Subsoil waters are by no means inexhaustible. Plant growth is dependent upon having available an adequate amount of soil moisture. Nothing should be done to deplete, unduly, the ground-water storage. Effective legislation and administration should be provided governing the tapping of underground water supplies.

The use of water for irrigation tends materially to increase the permanent settlement of the country. Consequently, in most instances, when irrigation requirements and other requirements conflict, the former are entitled to precedence. Hydro-electric power developed on somewhat distant streams may, by means of high tension transmission, be used for pumping water supplies where such are not available by gravity, and may thus facilitate irrigation development.

Not infrequently navigation interests are regarded as of much greater importance than power development. Any works contemplated for the improvement of navigation should be considered in their relationship to river systems as a whole. Expenditures should be carefully watched and precautions taken to ensure that improvements, so called, are not undertaken ostensibly for navigation, when in reality they are sought for the sake of such water-power benefits as may incidentally be developed thereby.

The fishing industry in British Columbia is one which demands that the best possible methods be used for its conservation. Provision requires to be made for the upward migration of adult salmon for spawning purposes and the downward passage of the young fish to the sea. Obstructions, such as dams, rock slides, log jams, etc., may have a disastrous effect upon this industry. Fishways should be provided. The whole question of fishways requires thorough investigation. Other fish besides salmon require conservation. It is not established that satisfactory means have been devised by which fish may successfully ascend over high dams—even over dams which do not exceed twenty to thirty feet in height.

The development of the mining industry during recent years has resulted largely through electrical energy being available through the development of provincial water-powers, and the future offers bright prospects for the further application of hydro-electric power to the various branches of this industry.

The pollution of inland waters must be most jealously guarded against. Mining, factory, and industrial wastes and sewage must not be permitted to foul inland waters. Debris and other waste resulting from logging operations are apt to cause serious log jams, which are a menace to public highways, bridges and also to power development.

The tourist traffic is a valuable provincial asset, not only because of the money actually spent by travellers, but because of the opportunity afforded of drawing attention to the various natural resources of the provinces. Consequently, every reasonable care should be taken to guard against the spoiling of shorelands through submergence; and further, care should be exercised in the design and construction of power works, making them where possible, harmonize with the general natural features of their surroundings.

In connection with the use of boundary waters, problems, from time to time, may arise necessitating consideration by the International Joint Commission. In this connection, therefore, it is especially desirable that physical data appertaining to such waters should be so collected as to be available for use in connection with such problems as may arise respecting waters which are classed in the Boundary Waters Treaty as "boundary waters."

Water Power Data

One of the chief objects in securing and publishing data respecting water-powers is to enable the owners of rights to determine the possibilities and limitations of their powers, and thus arrive at sound judgment respecting their possible uses and value. Another object is to enable prospective promoters to learn the general possibilities of various powers without the necessity of making costly independent preliminary surveys. Certainly if the Crown be the owner of water-powers it is of the utmost importance that it be informed beforehand upon essential facts connected with its water resources.

Broad Classification of Water-Powers

Although the amount of water-power is essentially determined by two basic factors, one, the hydrostatic head, or verical distance through which the water may fall; the other, the amount of water which may be made to operate upon the water-wheels, yet there are many characteristic features associated with water-powers which differentiate one power from another and which, respectively, determine their commercial and economic values. These features should be well understood.

Water-powers, from one viewpoint, may be considered on the basis of their probable uses. Those capable of being employed for supplying electrical energy for municipal and community purposes, such as lighting, heating, pumping, and certain kinds of manufacturing, should be regarded as having greater economic value than those situated where power is only usable in large manufacturing plants, the supplying of the raw material for which virtually means the destruction of nature's balance in the territory where the plants operate.

Again, the uniformity of the available flow in streams varies greatly. The St. Lawrence River, owing to the vast natural storage capacity of the Great Lakes, has the most uniform flow of any large river in North America, or probably in the world. The proportion of its flood to minimum flow is about 2 to 1. On the Winnipeg River, above English River, the ratio is 6 to 1; on the Ottawa River it exceeds 15 to 1; on the Columbia River, at the Dalles, Oregon, it is 28 to 1; on the Delaware River, at Port Jervis, N.J., it is 375 to 1; in British Columbia, on the Pend d'Oreille River, it is 16 to 1; on the Kootenay River, at Bonnington Falls, it is 25 to 1; on the Fraser River, at Lytton, it is 38 to 1; on the Campbell River, Vancouver Is-

land, it is 43 to 1. On the smaller watersheds the ratio is usually greater, and on some streams draining even areas of considerable size the minimum flow is zero. Other conditions being equal, water-power developments on a river like the St. Lawrence would be of very much greater value than developments on a river subject to such great variations of flow as, for example, the Mississippi.

Another feature is the possibility of being able to make a partial development of a power-site or portion of a stream, more cheaply than the same sized development could be made if constructed as part of a comprehensive scheme designed eventually to utilize all the available power. Thus, not infrequently, a partial development unwisely planned, has precluded subsequent full development, save at almost prohibitive cost. For example, suppose a certain power site is capable of yielding 10,000 h.p. If development rights are let to A for 2,000 h.p., to B for 1,000 h.p., and to C for 1,000 h.p., and A, B and C are allowed to design and construct their individual works irrespective of each other, or of the possible development of remaining 6,000 h.p., then it will probably become quite impracticable to get anything like the remaining 6,000 horsepower because of the damage that would be caused to the plants of B and C. On the other hand, if preliminary works are constructed with a view to utilizing, as occasion demands, any amount of power up to the full 10,000 horsepower, no such contingency as has been supposed could well arise. Consequently, regulations respecting power sites should be so framed as to require that preliminary installation of dams and other main works necessary for the control of the waters be made, having regard to the possible future development of the full water power that may be made available.

It is as unreasonable not to differentiate between water powers as it would be not to differentiate between timber tracts, mineral lands, fisheries, or any other natural resources varying in quantity, quality and situation.

It should not be forgotten, when making representations regarding the amount of power that may be available for any particular site, that it is necessary to know the conditions of the river at which the stated amount of power may be produced. The minimum or primary power, as it is frequently termed, is the amount of power that may be developed during the period of lowest flow. It has been defined as the amount of power which is available for every hour of every day of every year. What is frequently termed secondary power is usually many times the primary power. As very low-water conditions generally last for but a comparatively short portion of the year, it is usually possible to develop during the greater portion of the year a considerably larger amount than the primary power. Frequently, this larger amount can be effectively utilized for industries not requiring continuous plant operation.

The pre-determination of the probable amount of power which any particular water-power site may be made to yield is a problem that calls for more extensive hydrometric data that is furnished by scattered and non-consecutive measurements of stream flow, precipitation, etc. Also, it is very important that such cognate data be available as will enable a sound opinion to be formed respecting the relationship which any proposed power development may be to any other water interest or interests that may be involved. If some important relationship is overlooked, sooner or later its importance will demand recognition by those who proceeded in defiance of its just claims.

In estimating the amount of power that may be developed, hydrometric records of precipitation, temperature, run-off, etc., extending if possible over a period of fifteen or more years should be available satisfactorily to appraise the probable regimen of the water involved.

Financial Interests Should Increase Caution

Twenty years or so ago, when water-power began to be developed much more extensively owing to the advancement in the art of electrical transmission, there was not available anything like the body of streamflow and other hydrometric data that exist to-day. There was then more excuse for errors than now in engineering and oher estimates respecting the performance of water-power installations. Many large plants have proved financial failures on account of such errors. With all data now available relating to hydrological conditions, cost of construction, market possibilities, etc., it is clearly incumbent on those interested from the financial side of proposed developments, to exercise the same kind of common judgment they would display in collecting and appraising facts relating to any other set of circumstances. A financial agent could readily look over past statements of a concern and learn its lowest or highest yearly or monthly revenues, profits, etc. If he should find periods when the profits dropped to say 2 per cent. he need never be misled by the assurance of some enthusiastic promoter that profits in the concern "might be 20 per cent. and had never fallen below 5 per cent." Similarly any one interested in possible power development may now readily place himself in possession of data which will at least give some independent check upon representations that may be made respecting the physical magnitude and approximate cost of development of water power in which he may be interested.

Thus, by way of simple illustration, if a low flow of a stream has been recorded, this quantity in cubic feet per second multiplied by the total available head in feet and then divided by eleven, gives the low-water horsepower of the stream on the basis of 80 per cent. efficiency. Such a figure then constitutes a check upon any representations. Similarly, in connection with the storage benefits, no reliance should be placed upon vague statements to the effect that "ample storage is available." The flow corresponding to certain effective water storage may readily be checked. A depth of one foot on an area of one square mile is equivalent to a continuous flow of approximately 0.88 cubic feet per second for one year. Thus, a depth of ten feet of effective storage on a lake 10 square miles in area would maintain a continuous flow of 88 second-feet for a year or 176 second-feet for six months or 352 second-feet for three months. The extent to which such storage could be employed to equalize flow would, of course, depend upon how it could be coordinated to the run-off as distributed over any selected period.

Storage and Governing Factors.

Although the presence of numerous lakes does not necessarily imply the existence of considerable water-power there is nevertheless one very valuable feature likely to be associated with extensive water areas, namely: the existence of natural reservoirs where waters may be impounded for discharge under control. Obviously water-powers directly benefited by such storage reservoirs may be of much greater value than other powers not so favoured. This should be taken into special consideration when water-powers are being classified according to their economic values.

In British Columbia there are a large number of lakes. Of the known lakes, 100 are above 10 square miles in area. Many of these lie in long narrow valleys, and may rather be regarded as river expansions, as for example, the Arrow lakes, where at high water, there is a perceptible current in the shallowest parts. A large proportion of the lake area is situated in what has been termed the Lake district, which, with the exception of Babine lake and some lakes of the head waters of the Morice river, is nearly all tributary to the Nechako river.

When the subject of storage reservoirs is under consideration it should not be forgotten that Nature stores her waters otherwise than in lakes and rivers. Forest floors, extensive areas covered with plant growth and the great swamps of the country, also glaciers and snowfields, each and all constitute valuable water reservoirs. In such reservoirs there is a widespread and satisfactory distribution of waters which enables Nature to yield her supplies gradually and as required. A discreet conservation and utilization of such reservoirs will generally be found much more desirable than are some of the artificially constructed reservoirs where the liability to accidental destruction of dams or other works is always more or less of a menace.

Governments have been bestowing increasing attention upon the investigation of inland water resources and, during recent years, Canada has made great advancement in this work. Such work is essential in order to acquaint parties with the possibilities of the powers with which they may be dealing.

An Explanation of the Construction of Formulae

A Formula is Not a Mysterious Creation of Higher Mathematics, But Merely a Convenient and Simply Remembered Way of Stating the Rules of Procedure for Every-Day Problems

By T. H. FENNER, Associate Editor

ONE would think that a formula was self-explanatory, but it is surprising how many men use these things daily, without having any clear conception of the principles involved. Machinists, power plant men, and sometimes even draughtsmen, are content to take a set of letters and apply figures to them in the solving of everyday problems, not having any idea of how these combinations of letters have been derived, or what they stand for.

To begin with, a formula is simply a convenient means of stating a rule, which would be long and clumsy to write or remember in its original form. The derivation of this rule may be lost in the realms of higher mathematics, where none but the highest of highbrows may soar. That, however, does not prevent the average man from having an intelligent idea of the various factors contained in the formula, and their relation to one another. If the aforesaid average man had this knowledge he would not look so puzzled when a formula is presented to him in a slightly different guise to that with which he is familiar.

We have said that a formula is an abbreviated form of a rule, or statement. It is that, but it is also something more. It is a statement that the multiplication or division, subtraction, addition, or, perhaps, all four operations, on one set of factors, produces a result which is the expression of another factor. For instance a man wishes to know the size of spanner necessary to slack off a 3-4 hexagon nut. There is a rule for getting the size of the spanner across the jaws. The width of the spanner across the jaw must be equal to the diameter of the nut over the flats. Now this width is 1¼ inches, which is arrived at by taking the diameter of the bolt = ¾, adding to it half the diameter, and adding ⅛ inch. This rule applies to all nuts, so should be remembered. So to make it convenient we put it in the form of a formula thus: $D + \frac{1}{2} D + \frac{1}{8} = W$, or else

$\frac{3D}{2} + \frac{1}{8} = W$, which is more convenient. Better still is $1\frac{1}{2} D + \frac{1}{8} = W$. All these three expressions give the same result, and mean that when the indicated operations are performed on one side; the resulting figure is the size or quantity required. Thus the diameter of the bolt being ¾, D = ¾, so $(\frac{3}{4} \times \frac{3}{2}) + \frac{1}{8} = 1\frac{1}{4}$.

The Use of Signs

Perhaps to begin with, it is well to get a clear understanding of the various signs employed, to denote the different operations. Many men look askance at formulae, on account of signs being present in them that they have never before encountered. There is nothing to be afraid of for anyone who has mastered the rudiments of arithmetic in any of these characters. However, it is important that the operations be performed in exact accordance with the instructions conveyed by these signs, or results will be materially affected.

The commonest signs, of course, are the plus +, and minus —. Plus before a number means that that number is a positive quantity. A minus sign means that the number following is a negative quantity. Where several numbers are involved with these signs between them it means that the sum of all the negative quantities must be deducted from the sum of all the positive quantities. The result may be either positive or negative, and here is where the man with no knowledge of algebra may be puzzled. However, if he just casts his mind to a very familiar phenomenon of our winter climate he will understand it easily. If he looks at the thermometer on his way to work he may find it reads 15 below zero, or as it is usually printed, —15. By eight o'clock it has gone up to —10, and by 9 it has reached zero. At 10 it reads 5 above, or + 5, and stays there till 1 o'clock p.m. Then it comes down 5 degrees every hour, till at 5 o'clock p.m. it reads 20 below, or —20. Now, the average temperature for the 11 hours would be found by adding the reading at every hour and dividing by 11.

Now the sum will be $-15 + (-10) + 0 + 5 + 5 + 5 + 5 + 0 + (-5) + (-10) + (-15)$.

This will give $-55 + 20 = -35$

$\frac{-35}{11} = -3.18$, or an average temperature of slightly over 3 degrees below zero.

Now, if we imagine any other body or figure or scale beside the thermometer as having a positive value, a zero point, and a negative value, there will be no difficulty with the plus or minus.

The multiplication sign is occasionally a stumbling block to the novice, as, instead of using invariably the ×, the sign is omitted altogether, or a small dot, something like a decimal point, is used. Where the signs are omitted altogether is when a literary formula is used, but the dots are used between numbers. A figure before a bracket as 3(6x9), means that the product of 6x9 must be taken 3 times. Letters denoting values when placed together, as PLAN in the well-known formula for horse power, are read as P × L × A × N, and an expression like 323.4.64 would read 323 × 4 × 64. However, this latter method is not used very generally, either the × sign being used, or the sign omitted altogether.

The division sign is written in a variety of ways. The best known, of course, is the ÷ sign, which is the one we first become acquainted with. Then there is the line used as in fractional quantities, as $\frac{2}{4}$ which means that two is to be divided by four, or $\frac{8 \times 11}{6}$ which means that the product of 11 × 8 is to be divided by six. Again a line is sometimes used as 12/2, which means 12 is to be divided by 2.

These four are what might be called the cardinal signs. There are several others which must be made familiar to the eye, and their meaning to the memory, so that when they are encountered in formulae, there will be no difficulty in arriving at the correct solution.

Of these, the various forms of brackets are among the most important, and are often stumbling blocks to the tyro. Their meaning and the way in which they are used must be thoroughly understood, or correct solutions will be a matter of chance instead of certainty. Bracket signs are classified as follows: The parenthesis (), the bracket [], the brace $\left\{ \right\}$, and the vinculum ——. The generic term covering them all is " signs of aggregation ", and the meaning conveyed by any of them is that the numbers enclosed between them are to be simplified before any other operation is performed.

Take an expression such as $A = \frac{1}{2} (h + b)$, substitute figures for the letters, say, $A = \frac{1}{2} (3 + 5)$. This means that the sum of 3 and 5 multiplied by ½ will give the value symbolized by A. Take another: $4 + 6 (8 \times 4 + 5) - 2 = A$. Now, here is where a very important rule is illustrated, in connection with the multiplication sign. Two numbers connected together by a multiplication sign must be simplified before those connected by any other signs. In this case the solution step by step is, taking inside the brackets first, the product of 8 and 4, added to five, multiplied by 6, plus 4, —2.

The work is:

$4 + 6\ (8 \times 4 + 5) - 2 =$
$4 + 6\ (32 + 5) - 2 =$
$4 + 6 \times 37 - 2 =$
$4 + 222 - 2 =$
$226 - 2 = 224.$

Now, if the rule as to multiplying is not observed, the result will be entirely different. Suppose we were in simplifying the term in the brackets to add 4 and 5 before multiplying by 8, see what we should get.

The work would then be:

$4 + 6\ (8 \times 4 + 5) - 2 =$
$4 + 6\ (8 \times 9) - 2$
$4 + 6 \times 72 - 2$
$4 + 432 - 2$
$436 - 2 = 434.$

Now, when simplifying a formula in which several terms are bracketed, always simplify the terms in the inner brackets first.

Take the formula for finding the area of a segment of a circle, or rather one of the formulae, of which there are several.

$A = \frac{1}{2}\ [lr - c\ (r - h)]$

Substituting figures $A = \frac{1}{2}\ [8 \times 4 - 3\ (4 - 2)]$

Simplifying $A = \frac{1}{2}\ [8 + 4 - 3 \times 2]$
$= \frac{1}{2}\ [32 - 6]$
$= \frac{26}{2} = 13$

Take another a little more complicated, as follows:

$$x = 4\left\{3 + [6 \times 9 - (2 + 4 + 3 \div 3)]\right\}$$
$$x = 4\left\{+ [6 \times 9 - 3]\right\}$$
$$= 4\left\{3 + [54 - 3]\right\}$$
$$= 4\left\{3 + 51\right\}$$
$$= 4 \times 54$$
$$= 216$$

The rule to observe always is to simplify the expression in the innermost bracket first of all and when simplifying any expression to perform the indicated multiplication first, and the addition and subtraction afterwards. We have not dealt with the last sign of aggregation, the vinculum, because it is not used as a rule except in connection with the root or radical signs. We will consider these, and the index signs, and then give some examples of the use of the vinculum.

The radical and index signs are used when a number is to be reduced to a primary number, or root, from a higher power, or to be raised from a root to the higher power. The radical sign $\surd$ before a number indicates that the square root of that number is to be extracted. The sign with a small figure on the side indicates that the root corresponding to the number is to be taken. Thus $^3\surd$ indicates cube root, $^4\surd$ indicates fourth root, $^5\surd$ indicates fifth root and so on.

Conversely, the small or index figure placed above a number indicates that the number must be raised to the power indicated. Thus 2^2 indicates two taken two times, 2^3 indicates two taken three times, 2^4 means two taken four times, etc. Now sometimes an index may be seen like the following: $5^2/_3$. That means that the cube root of five squared is required, and could be written $^3\surd 5^2$.

There is no need to perform the actual arithmetical operations, for there are tables published which save all that labor. All one would need to do would be to turn up the table, see the square of 5=25, and the cube root of 25=2.924, etc. Now the vinculum is used when the root of several numbers is required. For instance $^3\surd(8x9) - 7x6$ means that the cube root of the product of 8x9 minus the product of 7x6 is to be taken. Take the formula for the approximate operimeter of an ellipse, which is

$$P = \frac{\pi\surd D^2 + d^2}{2} - \frac{(D - d)^2}{8.8}$$

That is a good example of the use of the vinculum, the bracket, and the index figure, coupled with the use of a sign which is met with almost constantly. That is the Greek letter π, pronounced pi, and used to denote the figure with which the diameter of a circle must be multiplied in order to find the circumference. This is a constant quantity 3.14159, commonly written as 3.1416, or if expressed in fractions as $\frac{22}{7}$, which is not so accurate, and therefore less used. In a circle of diameter d, the circumference is πd, or $2\pi r$, where r is the radius.

There are several other Greek letters in common use by mathematicians, which cause the ordinary man to throw up his hands and retire when met with. However, there is no end of this. They are merely used as symbols and are no more mysterious than the ordinary Arabic figures.

For instance, there is the Greek letter Θ, pronounced theta. This is nearly always used to denote an angle. For instance, if we are engaged in solving some problem which involves an angle of 35 degrees, instead of writing this in full every time we came across it, the letter Θ would be employed. If we have more than one angle another Greek letter is employed for the second angle, the letter Φ, pronounced phi. Many other Greek letters are used, but probably these are sufficient for the time being. All the writer wants to show is that there is no need to look upon a formula as being unworkable because some of the signs are not familiar.

As to the derivation of formulae, the full understanding of these often entails a knowledge of first principles beyond the ken of the non-mathematical. However, many of the every-day formulae in use by machinists, power house men, etc., are easily traced back to their beginning, and it is useful practice to get in the way of doing this. It helps a man to known why a thing is, in addition to knowing that it is. The mental stimulus obtained by reasoning things out is also a benefit. For instance, many machinists know that the speed of the last shaft on a train of gears is equal to the speed of the first shaft multiplied by the diameter of all the drivers and divided by all the followers. Why should it be? Suppose we have a line shaft running 240 revs. We have a 12-inch pulley driving a 24 on the second shaft, and a 10-inch from that driving a 25 on the third shaft, and a 6-inch driving a 12-inch on a fourth shaft. Let a, b, c represent drivers and d, e, f the followers. Then

$\frac{a, b, c}{d, e, f} \times 240$ will be speed of the last shaft. That is $\frac{12x10x\ 6}{24x25x12} \times 240 = 24.$

That formula is simply a statement of the ratio of the first speed to the last as can be seen by taking each shaft separately. The first shaft goes 240 revs. The ratio of the gear on the first shaft to that on the second 12:24 or 1:2. The second shaft, therefore, goes $\frac{240}{2} = 120.$ The second ratio is 10:25 or 1:2½. Therefore the third shaft goes $\frac{120}{2\frac{1}{2}} = \frac{240}{5}$ = 48. The last ratio is 6:12 or 1:2. That gives $\frac{48}{2} = 24$ as the final speed. Now the ratio is 24:240 or 1 to 10 for the whole range. The first ratio was 1:2, the second 1:2½ and the third 1:2. Multiply these together, 2x2½x2, gives 10. Is it plain now why all the followers divided into all the drivers give the required speed? The same rule applies to the change gears on the head of a lathe. The diameter of the gear on the driving spindle bears a certain relation to the driven gear on the stud. The driver on the stud bears a definite relation to the driven on the lead screw. How is this expressed? Let the spindle driver be called "A," the driven gear on stud "C," the driver on stud "F," the driven on lead screw "D". The lead screw has "G" threads to the inch. The number of threads to be cut are "N."

Clearly, the threads cut per inch will depend on the ratio of "A" to "C" and "F" to "D." The other factor will be the pitch of the lead screw. Now if we have a gear on the spindle with 21 teeth, and the driver "F" on the stud has 60 teeth, while the driven gear "C" on the stud has 42 teeth, the driven gear "D" on the lead screw 72 teeth, we can find the ratio of the lead screw speed to spindle speed. Thus $\frac{42x72}{21x60} = \frac{12}{5}$. That is a ratio of 2 2/5 to 1, so that for every five revolutions of the lead screw we get 12 revolutions of the job. Now if the lead screw has five threads to the inch the cutting tool will travel one inch along the job while the leading screw turns five times. But while this has taken place the job has turned 12 times, thus cutting 12 threads to the inch. All this

is expressed by the formula $n = \frac{c \times h \times g}{a \times f}$.

The next time you have to cut a thread see if you can realize the relation of the spindle speed to the threads cut on the job.

Take the good old formula for horse-power, so familiar to most power house men. Horse-power is a rate of doing work. Work is force, multiplied by displacement. The steam pressure is the force and the piston speed is the displacement. Work is measured in foot pounds, horse-power in foot pounds per minute. Hence the piston speed per minute multiplied by average mean pressure is work in foot pounds and divided by 33,000 is horse-power. Thus

$$\frac{PLAN}{33{,}000} = H.P.$$

we get the familiar Now if we saw it written C P = I.H.P. it might cause wonder, but just think. In an automatic cut-off stationary engine, the only variable is the pressure. If we take the stroke cylinder area and number of strokes and multiply them together, and divide by 33,000, we get a decimal quotient, which has only to be multiplied by the pressure to give the required horse-power. Surely, a time-saver.

There is nothing new in this article to many of us, but to quite a few who have been discouraged from pursuing a line of study through encountering a strange formula, it may serve to lighten an otherwise dark spot.

The Canadian Engineering Standards Association

IT IS not generally known that we have in Canada an association known as the Canadian Engineering Standards Association.

The Purpose of the Association

The Canadian Engineering Standards Association was formed in 1919 with the object of carrying out in Canada, for the benefit of Canadian industry, work similar to that done in England by the British Engineering Standards Association, which has proved of such great industrial value. The Canadian Engineering Standards Association is not a Government institution, although it is recognized by the Canadian Government. The members, who serve on its committees gratuitously, are qualified by their technical and industrial standing to represent the interests of manufacturers, engineers and users, and are nominated by such bodies as the Canadian Manufacturers' Association, the Canadian Mining Institute, the Engineering Institute of Canada, the engineering schools of the universities, the railway services, important industrial firms and the great purchasing departments of the Canadian Government.

The association has now been incorporated by Dominion charter.

The association is supported by contributions from the technical and industrial societies interested, as well as from individual firms, and these are supplemented by a grant from the Dominion Government.

Method of Work

When a request or suggestion is received from some responsible firm or person to the effect that the formulation or revision of a Canadian standard is desirable, the association confers with the various interests likely to be affected by the establishment of such a standard, and arranges for the organization of a committee to consider the matter. This committee includes representatives of the producers and users of the standard in question together with such technical advisers as may be considered desirable. The selection of such a working committee is accomplished through the proper sectional committee of the association under the chairmanship of a member of the association. If the committee so formed recommends the adoption or modification of a standard, its findings are reviewed by the association, the main committee of which must be thoroughly satisfied that full consideration has been given to the subject before it authorizes publication by the association.

The actual discussions as regards technical details are thus carried out by specially chosen representatives of the manufacturers and purchasers, and the various interests, whether of the producer, the user, or the engineer, are safeguarded, since all these parties have a voice in the decisions reached. In this way it is clear that before a report, defining a Canadian standard is issued or modified, the effective approval of all concerned will have been obtained.

The services of the various sectional and sub-committees are of course available for the periodic revision of their reports, this being necessary in order to avoid any risk of retaining a standard in use after improvements or changes of practice have rendered it obsolete in any respect.

There is reason to believe that the success of the work done by the British Engineering Standards Association in the past has been largely due to the careful way in which its main committee has reviewed the work of its various sectional and other committees.

The C.E.S.A. standard specifications will, as a rule, contain simply the technical clauses necessary for the purchase of the product to which the specification relates, together with such tables and diagrams as may be required for their explanation.

Meaning of Standardization

In order to avoid misunderstanding it may be pointed out that the term "standardization" refers primarily to the preparation of such designs, dimensions or specifications in industrial, manufacturing, or construction work as will be generally accepted and worked to by all concerned. In the case, for instance, of a machine component, if its principal dimensions and characteristics are standardized, the number of types or patterns to be made or kept in stock commercially is at once reduced, lessening accordingly the cost of manufacture and handling, with corresponding saving and convenience to users.

An example of economy attained in this manner would be afforded if the various Canadian railway administrations would agree with the steel makers to adopt a standard Canadian section and specification for rails and track fastenings. This action would not only reduce the number of different rolls to be cut and used by the rail mills, but would enable material to be rolled for stock direct from the billets at less cost and with a certainty that they would be acceptable to any railway. The railways would simplify their practice, avoiding the use of rails and fastenings differing in form and material only in comparatively unimportant details, and would benefit by the higher and more uniform quality of the product. Some progress towards this desirable result has already been made.

Similar opportunities for substantial saving in the cost of manufactured products and for protecting the interests of the user now occur in many other Canadian manufacturing industries wherever articles and materials may be so standardized by common agreement between the producer and user as to permit their production in economical quantities while still satisfying the requirements of the purchasers. No organization has hitherto existed in Canada for bringing these various interests together and inducing them to agree on a mutually satisfactory design or specification.

The Canadian Engineering Standards Association, like the British Engineering Standards Association, does not as a body decide upon the details of its standards, but organizes and reviews the findings of a representative committee for each particular standard suggested, thus insuring that all interests are properly considered and making certain that any recommended standard has been carefully investigated before it is issued. No standard that is not based on mutual agreement arrived at in this manner is likely to receive general endorsement and adoption.

Since the commencement of their activities three months ago, great progress has been made.

Requests for action have been received and committees have been formed, or are in process of formation, dealing with the following subjects: Aircraft parts, electrical work, rails and track, wire rope, steel bridges and construction, with the view of obtaining agreement on Canadian specifications or standards which will be acceptable to all concerned.

In this work, consideration will of course first be given to any existing specifications or standards which have proved satisfactory in Canada, Great Britain, and the United States for similar work.

This association has been requested by the British Engineering Standards Association (the corresponding organization in Great Britain) to undertake the distribution of its publications in Canada, and for this purpose has been furnished with most of the reports of the British Engineering Standards Association. The list to follow does not include all the publications of the British Engineering Standards Association, but covers those of most recent issue. Copies are for sale at the prices stated.

Report No. C L 3750. "Interim Memorandum on French Metric Screw Threads for Aircraft Purposes," 15c net.

Report No. 10-1904. Revised July, 1918. "British Standard Tables of Pipe Flanges," 25c net.

Report No. 15-1912. Revised August, 1912. "British Standard Specification for Structural Steel for Bridges, etc., and General Building Construction," 25c net.

Report No. 21-1909. Revised November, 1909. "Report on British Standard Pipe Threads for Iron or Steel Pipes and Tubes," 25c net.

Report No. 37-1919. Revised January, 1919. "British Standard Specification for Electricity Meters," 25c net.

Report No. 41-1908. "British Standard Specification for Cast Iron Spigot and Socket Flue or Smoke Pipes," 25c net.

Report No. 44-1909. "British Standard Specification for Cast Iron Pipes for Hydraulic Power," 25c net.

Report No. 45-1917. Revised September, 1917. "Report on British Standard Dimensions for Sparking Plugs for Internal Combustion Engines," 25c net.

Report No. 46-1909. "British Standard Specifications for Keys and Keyways," 25c net.

Report No. 63-1913. "British Standard Specifications for Sizes of Broken Stone and Chippings," 25c net.

Report No. 65-1914. "British Standard Specification for Salt-Glazed Ware Pipes," 25c net.

Report No. 71-1917. "Report on British Standard Dimensions of Wheel Rims and Tyre Bands for Solid Rubber Tyres for Automobiles," 25c net.

Report No. 72-1917. Revised September, 1917. "British Standard Rules for Electrical Machinery." (Excluding motors for traction purposes), 25c.

Report No. 74-1917. Revised September, 1917. "British Standard Specification for Charging Plug and Socket for Vehicles Propelled by Electric Secondary Batteries," 25c net.

Report No. 75-1916. "British Standard Specifications for Wrought Steel for Automobiles," 25c net.

Report No. 76-1916. "British Standard Nomenclature of Tars, Pitches, Bitumens and Asphalts When Used for Road Purposes and British Standard Specification for Tar and Pitch for Road Purposes," 25c net.

Report No. 82-1919. "British Standard Specification for Starters for Electric Motors." (Face-plate type), 25c net.

Report No. 84-1918. "Report on British Standard Fine (B.S.F.) Screw Threads and Their Tolerances," 25c net.

Report No. 88-1919. "British Standard Specification for Electric Cut-Outs for Low Pressure, Type O," 25c net.

These reports are concise and complete and well worth the price.

Requests for copies of any of the above should be addressed to:

Heat Value of Coal Determined by Ash Content

A Definite Relation Can be Established, for Coals of the Same Composition, Between the Ash Content and Heat Value. This Article is Published Through the Courtesy of "Combustion"

By FRANK G. PHILO

COALS having a fairly constant ratio of the various combustible constituents such as carbon, sulphur, and volatile, show quite a definite relation between ash content and heating value. Tabulation of several hundred coal analyses has shown, however, that the heating value of most coals decreases in a somewhat greater proportion than might be expected from the ash contents. This is usually due to the impurities external to the coal particles themselves, such as pyrites, bits of various rocks, etc. Pyrites, for instance, contains sulphur which, although combustible, has a very low heating value as compared with carbon. Carbonate rocks such as limestone, upon being heated, give off CO_2 which would indicate as combustible, but have no heating value.

The above references to pyrites, etc., are only made to indicate roughly why the heating value of coals decreases in a slightly greater proportion than would be expected from the increase in ash. No attempt is here made to go into the chemical side of coal analysis as the following data treats coal purely as a mechanical mixture of combustible and ash.

Some advantages of using ash content as an indication of heating value are: (1) Less laboratory equipment required, (2) less time required for the test, (3) several samples can be analyzed simultaneously, (4) less skill required on the part of the tester to do accurate work.

The writer does not advise against the use of the calorimeter for work of a very accurate character, such as boiler trials, etc. However, the ash "content" method of calculating heating value has

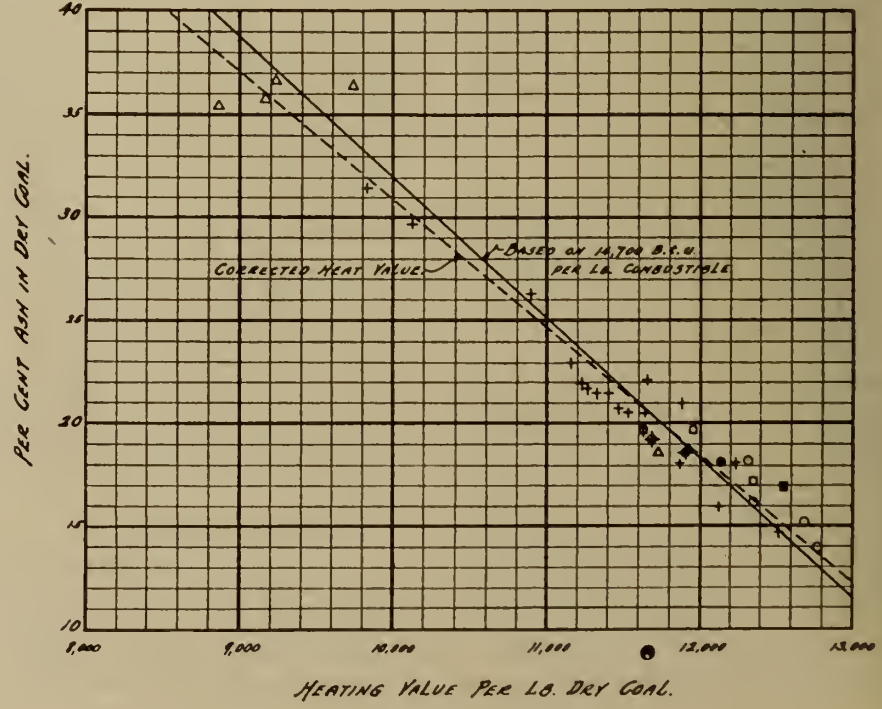

CHART NO. 1

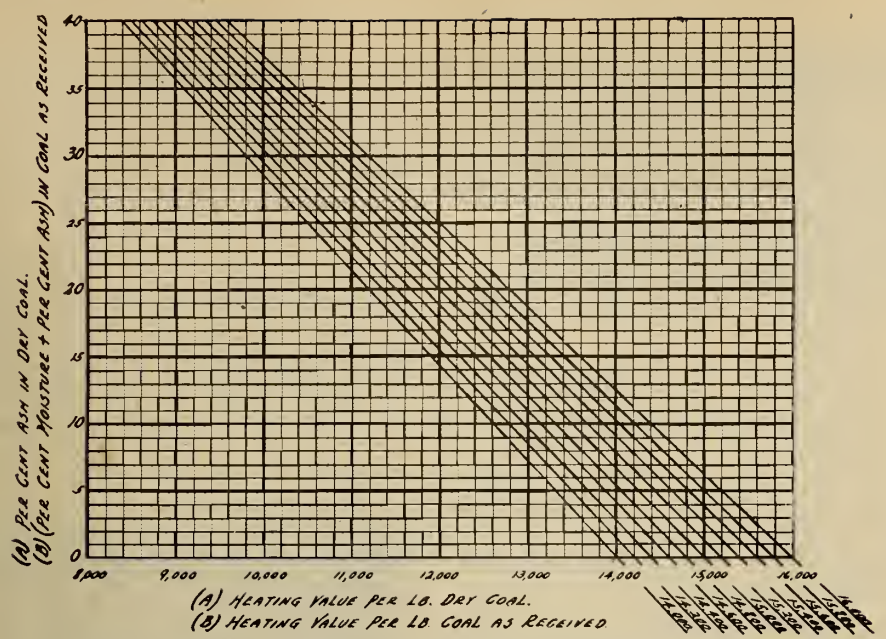

CHART NO. 2.—SHOWING RELATIONS BETWEEN PER CENT. DRY ASH AND HEATING VALUE OF COAL

proved in practice the most desirable for the operating engineer. For instance, a number of cars of coal have been delivered and are awaiting unloading. Which shall be delivered to the bunkers and which delivered to the storage yard (to which the best coal should go to cut down handling costs)? Samples are properly taken, and within a fraction of the time required by calorimeter, the ash content is determined, heating value calculated, and disposition of the cars of coal is under way.

In a station operated by the writer, the ash determination is made on each barge or car of coal before unloading. In the past year several possible interruptions of service were avoided by locating among a number of barges of coal, several barges which had an ash content of 35 to 38 per cent. These barges were consequently pigeon-holed till periods of light load and then used.

The coals shown as points on Chart 1 are No. 3 Buckwheat taken at random from deliveries from the various districts of the anthracite field. All are Pennsylvania coals. The solid line is the line of constant heating value per pound combustible, which for anthracite averages 14,700 B.t.u. per pound. The broken line is the line of actual combustible heating value, the difference between the two lines being caused by sulphur, etc., as stated above.

Having a number of coal analyses and heating value determinations by calorimeter, a similar chart may be constructed for any coal, care being taken to have all coals shown of the same class. Having the heating value per pound combustible for any class of coal, the heating value corresponding to any per cent. ash may also be determined from Chart 2.

The accompanying table and formulas may be used, if desired, in place of Chart 1.

Factors for Heating Value Determinations of Anthracite Coal

Per cent. Dry Ash	Factor	Per cent. Dry Ash	Factor
10	1.015	26	.991
11	1.014	27	.989
12	1.012	28	.988
13	1.011	29	.986
14	1.009	30	.985
15	1.008	31	.983
16	1.006	32	.982
17	1.005	33	.980
18	1.003	34	.979
19	1.002	35	.977
20	1.000	36	.975
21	.999	37	.974
22	.997	38	.972
23	.995	39	.971
24	.994	40	.969
25	.992	..	...

Heating value per lb. dry coal = HVDC.

HVDC = Factor [(100 — Dry Ash) × 147].

Heating Value per lb. coal as received = HVWC.

HVWC = B.t.u. per lb. dry coal (100 — Moisture in coal as received).

As can be seen from Chart No. 1, the use of the factor is not important for coals whose ash contents lie between 10 per cent. and 25 per cent.

Eliminating the factor: HVDC = (100 — Dry Ash) × 147.

HVWC = HVDC (100 — Moisture).

The manufacture of nitrates by the fixation of atmospheric nitrogen is rapidly becoming a world industry. In this the Japanese are keeping in line with American and European enterprise. D. Takamine has, it is said, purchased, on behalf of Japan, the American modification of the Haber process. It is intended to instal a plant to use this process for the production of synthetic ammonia. The Japanese Government has provided means for the building and maintenance, in a suburb of Tokio, of an experimental laboratory for research concerning the conditions of the fixation of nitrogen.

WATERPOWERS OF BR. COLUMBIA

(Continued from page 558)

A number of factors, such as character of use, uniformity of flow, the making of but partial development in a manner prejudicial to future complete utilization, failure rightly to differentiate between primary power and secondary power, etc., etc., have been noted and attention drawn to the necessity for reckoning with such factors.

Hydrometric data extending over a sufficient period of time should be available, and conclusions involving important procedure should not be predicted upon scattered and insufficient records. Topographic maps should also be available.

Those interested from the standpoint of the investor may let the expenditure of ordinary effort place themselves in a position, independently, to check and form a judgment respecting some of the basic engineering factors involved in any power project under consideration.

Failure rightly to assemble or interpret essential physical data has been responsible for many serious failures, and has resulted in great financial loss.

No reliance should be placed upon general statements setting forth the existence of vast undeveloped waterpowers. The total amount of waterpower capable of economic development is much less than popularly assumed and most of the valuable sites are already under development or control by various interests. Attention has been directed to the concentration of control of waterpowers as proceeding rapidly in the United States, and the need has been pointed out that those interested in the conservation of our water-powers should be alert to see that the same menace to public welfare does not operate in Canada. Much of this concentration of control has taken place during a time when general statements representing the existence of large reserves of potential water-power were being presented to the attention of the public and were receiv- general acceptance.

The importance of storage has been pointed out, and the possibilities of storage causing damage to riparian owners has been emphasized. Government provision for a flowage easement along the shores of the lakes and rivers would, to some extent, protect settlers against loss, and would protect the government itself against claim for damage by overflow.

Many of the features touched upon have been safeguarded in the comprehensive water legislation of the province of British Columbia—a subject dealt with in the following chapter.

SULPHUR IN COAL

The University of Illinois have issued bulletin No. 111 on "A Study of the Forms in Which Sulphur Occurs in Coal." This publication deals with the different forms in which the sulphur is formed and the method by means of which the values can be estimated.

Heating System in a Montreal Church

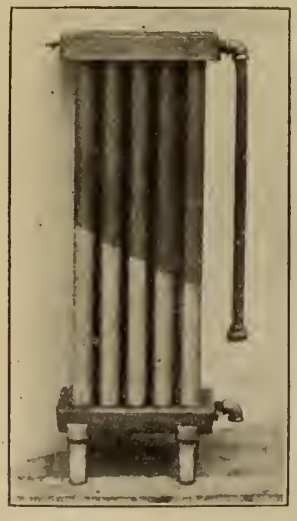
A Description of the Design and Operation of a New Type of Heating System. Rapid Circulation and Low Volume of Water Result in Economical Operation

By J. H. RODGERS

THE Montreal General Tool Company, of Montreal, has secured the contract for the heating of the new church of St. Augustine, at Notre Dame de Grace. As this is the first installation, on a large scale, of this particular method of heating, a brief description of its design and operation may be of interest.

Owing to the severe climate conditions in this section of the country, during the winter months, the heating of houses, offices, factories and other buildings, is very often a problem of no mean magnitude. Hot water and steam heating are the systems most generally adopted, but despite the recognized efficiency of these two methods, there are still many weak points that engineers are continually striving to overcome.

Some sixty years ago the first installation of a modern hot water heating system was installed, and since that time little change has been effected in the general fundamental principles of hot water heating. With the possible exception of the Honeywell method, which utilizes mercury as a medium for increasing the water circulation, no adequate system has been devised to add materially to the efficiency of existing systems. The elementary essential of successful hot water heating is to minimize the quantity of water passing through the system, and by so doing, reduce the consumption of coal, or other fuel, and thereby increase the boiler efficiency and economy. In many so-called modern systems the movement of the water through the pipes and radiators, is very sluggish, owing to the large body of water contained in the system, and it is generally understood that water at rest is a poor absorber of heat, but when in motion has a large capacity for carrying heat.



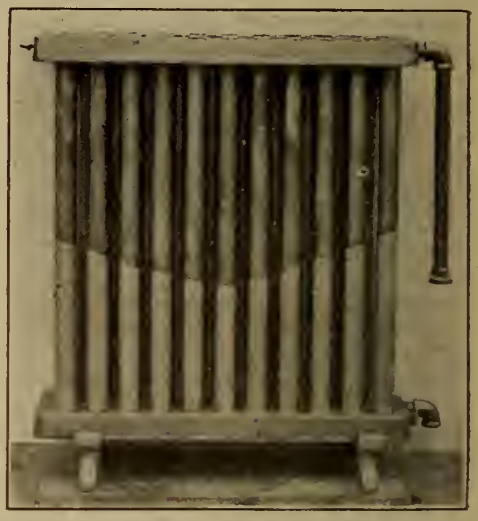
SMALL RADIATOR OF THE NEW TYPE

Working on the assumption that a water heating apparatus containing a small quantity of water, circulating rapidly, would be the most effective and economical, J. E. M. Brissette, of Montreal, has developed a type of radiator that reduces the volume of water therein to about one-quarter of that contained in the ordinary system, and at the same time adds about 75 per cent. to the radiating surface. This system is known as the "Victory" Water Heating System, and the ratio of the circulation to that of the ordinary system is practically 8 to 1, in other words the water in the Victory system circulates eight times through the system while the water in another system is passing once through the piping and radiators. By increasing the velocity of the water through the system it is changed much oftener over the heated surfaces of the boiler plates or tubes; therefore, the B.t.u. contained in the coal, or other fuel, is transmitted through the metal and more rapidly absorbed by the moving water, thus minimizing the loss of heat by excess gases passing up the stack.

The inventor of the "Victory" system of hot water heating, claims to have hit upon the most effective means of utilizing the heat units in the hot water for general heating purposes. The principle of the radiator design is to reduce the volume of water passing through the system and at the same time increase the heating surface exposed to the atmosphere. The heat distributed by the outside pipes is similar to that of the ordinary method, but the additional heating surface obtained by the use of the inner tubes, adds considerably to the effective distribution of the heat. Unlike the piping used in the ordinary systems, the seamless steel tubing used in the Victory radiators is very thin, reducing the amount of metal to be heated, thus developing heat more rapidly and more intense. Owing to the small water space between the inner and the outer tubes, the volume of the water in the system is considerably less than in many others, so that the more rapid transfer of heat, from the water to the atmosphere, causes a corresponding increase in the water circulation.

The efficiency of any radiator is its ability to waste heat; in other words, the more rapidly the temperature of the water in the system is reduced, the more effective the radiator will be, and consequently more economical.

The construction of the radiator is shown in the line drawing herewith. The size of the unit will vary to suit the conditions under which it is installed, but the general design is similar in every case. The cast iron heads are so proportioned that circulation is uniformly maintained in each and every vertical radiating pipe, and owing to the small space between the inner and the outer tubes, the film of water is very easily heated, and the movement of the water, due to the temperature change, is much more rapid than in the ordinary system. The cast iron headers (top and bottom), are made to conform to specific conditions, but the tubes are of uniform size, 1 inch and 1¼ inches, for inner and outer respectively, the lengths being made to suit the different heights required. These tubes are expanded in holes in the headers, which are previously drilled and reamed to the size desired.

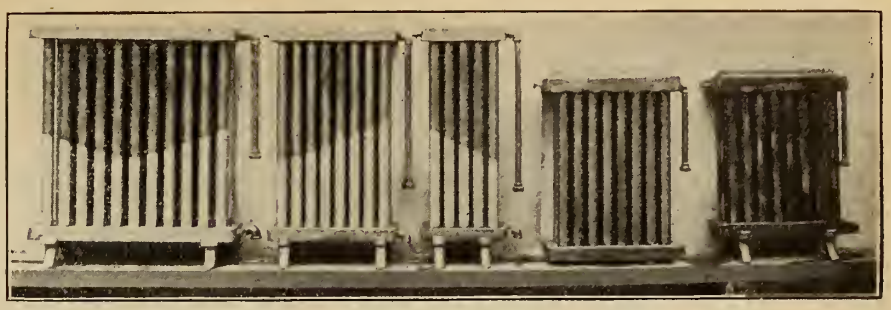


LARGE RADIATOR

The heating of the St. Augustine Church calls for 20,000 feet of radiation, and the volume of water in the entire system will be 180 gallons. For a similar radiation on other systems, the approximate quantity of water would be close to 1,800 gallons. The water in the system will circulate completely through the system, at normal heating temperature, every 15 minutes, while the larger body of water in the ordinary way would require about two hours.

Another interesting feature in connection with this particular installation will be the use of a 50 h.p. Talbot boiler, oil fired, and adapted for gravity circula-

tion. Under ordinary conditions this type of boiler operates on the contra-flow principle, but owing to the absence of forced circulation, the change to the natural method was found advisable. The Montreal General Tool Co. do not propose engaging in the heating business, their intention being to manufacture these radiators for the trade. This initial installation is solely for practical demonstration of the system on a large scale.



A GROUP OF VICTORY RADIATORS

SOME ELEMENTS OF ECONOMY IN THE BOILER ROOM

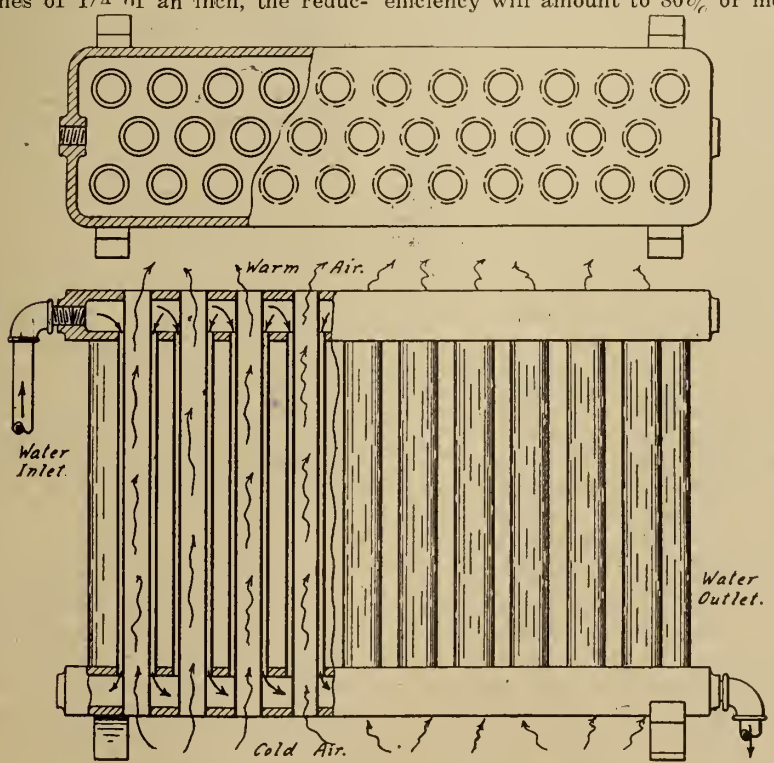
By F. A. McLean

Many a boiler is condemned and thrown out of service long before its useful life would have been ended had it been properly cared for and a few simple steps taken to keep it in good condition. Too often the fires are pulled and the water blown out of the boiler while the brick work is still hot, with the almost inevitable result that the tubes are soon buckled or split.

In many plants it is customary to scale the boilers at stated intervals of every six months or more, and while in some cases this may be all right, in the majority of instances it is not, and it would therefore be better to inspect the boilers frequently and have them cleaned as often as it seems necessary, whether it be three days or three months, instead of waiting until it is an absolute necessity. Many men do not realize the importance of keeping the tubes free from scale, but when one stops to consider that a layer of scale 1/64 of an inch thick will reduce the efficiency of the boiler 5%, while if this allowed to reach a thicknes of 1/4 of an inch, the reduction in efficiency will reach as much as 86% or more, it is readily apparent that the prevention and removal of this scale is a subject worthy of very careful attention.

There are on the market at present a number of chemical compounds which are of considerable value in preventing the formation of scale, as well as several sizes and types of scaling equipment designed for operation on steam or compressed air, the respective merits of which are well worth looking into. Sometimes a boiler is thrown into the discard or sold at a sacrifice, on the ground that it has not sufficient capacity to do the work required of it, when if it was thoroughly cleaned it would be plenty large enough for the work in hand.

With the high cost of fuel which prevails at the present time, it seems well to remember that the output of the boilers will be reduced about 9½% by a layer of soot on the heating surfaces 1/32 of an inch thick and where this is allowed to gather until it reaches a thickness of 1/4 of an inch, the reduction in efficiency will amount to 80% or more.



CONSTRUCTION OF NEW TYPE OF RADIATOR

In most plants steam is used for blowing out the boilers, and the water of condensation makes this a nasty job, and at the same time the heat of the steam makes the hose hard to hold, which probably accounts for the fact that the men in charge of the boilers do not feel inclined to clean the boilers as often as they should. Where compressed air at a presure of 80 to 100 pounds per square inch is available, it will be found of particular value for this class of work and, at the same time, it provides a ready source of power for the operation of mechanical tube scaling equipment.

Where automatic stokers are installed, it sometimes happens that they are not in as close harmony with the rest of the plant as they should be, due to the installation of a type of stoker which is either too large or too small for the boilers in use, or one which is not adapted to handling the kind of fuel available. When properly installed, the automatic stoker is a very useful piece of power plant equipment, but it is well to remember that a style which works very well with a certain type of boiler and fuel, may be a failure when used on another type of boiler, or with a different grade of fuel, and care should be taken to see that the stoker is not like the whistle on Mark Twain's steamboat, which caused the boat to stop every time it was blown.

In some plants a considerable amount of heat is lost through cracks in the brick work of the boiler setting, and it is therefore a good plan to see that this is as tight as possible. When properly fitted, dampers will often save as much as 25% of the heat which would otherwise be wasted. Some husky firemen pride themselves on the amount of coal they can shovel per hour, rather than on the amount of steam they can produce per ton of coal consumed per hour. Generally speaking, it is better to fire a little at a time instead of by fits and starts. It is interesting to note that one of the large automatic stoker manufactures in the United States estimates that fully 80% of the boiler plants of the country are overloaded, either through ignorance, or by the addition of equipment which was not thought of at the time the installation was made. This is false economy, and is not fair to the builder of the boiler. When the boilers are purchased, it is well to provide a little leeway to take care of any additions to the plant which may seem necessary at some time in the future.

The Keeping of Books in the Power Plant—I

The Subject of Accurate Cost Records is of Much Importance in Power Plant Economy. To be of Use They Must be Consulted in an Intelligent Manner and Carefully Compiled in the First Case

By ROBERT JUNE

ITEMIZED records of plant equipment, plant performance, and costs of operation, are of vital importance in the operation of all power plants if the most economical results are to be obtained. It should go without saying, but unfortunately does not in many cases, that records are of no value merely as records. If they are simply compiled and filed away without ever being consulted they are worse than useless.

Records are of value for two purposes:

(a) To give the management comparative data on the performance of a power plant from time to time so that it will be possible to tell just what power is costing.

(b) To place information in the hands of the chief engineer and his principal assistants, which will enable them to cut production and maintenance costs and to choose additional equipment when required, wisely.

The records to be kept may be divided into the following general classifications:

1. Permanent specifications of all equipment.
2. Record of load demands.
3. Costs of operation.

Taking up the first of these, it is probably safe to say that with only a very small percentage of power plants are proper permanent specifications of equipment kept on file. Yet the value of these will hardly be gainsaid by any operating man who has ever had to make repairs quickly or who has been called upon for advice in connection with power plant extensions. Probably the best system to employ is that of maintaining tabulated specifications on a series of large cards kept in a permanent index, but it is just as practical to record the data in a good-sized book, if that seems the more desirable. As typical of the statistics that should be maintained, the following are examples of boilers, feed-pumps and soot blowers:

Specification Data—Boilers

Make of boiler, Stirling.	
Total number in plant	6
Shop numbers	..
Date of installation:	
2	October, 1909
2	March, 1913
1	January, 1917
1	January, 1917
Weight of boilers	63,500 lbs.
Cost of boiler and fittings:	
2	$11,200.00
2	12,300.00
2	16,400.00
Cost of foundation and setting:	
2	$3,200.00
2	3,650.00
2	4,225.00
Rated horsepower	412
Steam pressure gauge	200
Safety valve pressure	210
Type of safety valve	(two) Pop.
Heating surface, sq. ft.	3,800
Superheating surface, sq. ft.	300
Number of steam drums, 3	36 in.
Diameter of safety valve	4 in.
Diameter of steam nozzle	10 in.
Diameter of feed pipe	2 in.
Diameter of blow-off	2½ in.
Type of stoker	B. & W. Chain Grate
Temperature of feed water	200° F.
Number of tubes	363
Diameter of tubes	3¼ in.
Length of tubes	13 to 15 ft.
Steam space	112 cu. ft.
Water space	700 cu. ft.
Draft	mechanical
Maximum draft	3 in.
Height of setting	18 ft. 2 in.
Length of setting	17 ft. 8 in.
Width of setting	16 ft. 4 in.
Thickness of walls, side	20 in.
Thickness of walls, back	15 in.
Number of fire bricks	6,860
Number of common bricks	22,400
Distance between batteries	4 ft. 6 in.
Distance from back of boiler to wall	15 ft.
Distance from front of boiler to wall	14 ft. 2 in.

Specification Data—Feed Pumps

Make of pump	Goulds
Number in plant	Three
Overall dimensions	3 x 4 x 12 ft.
Cost of installation—	
One	$1,125.00
One	1,250.00
One	1,490.00
Displacement per stroke	56/100 cu. ft.
Strokes per minute	12
Steam pressure	200 lbs.
Back pressure	½ lb.
Diameter steam cylinder	16 in.
Diameter water cylinder	10 in.
Stroke	12 in.
Diameter of suction	8 in.
Diameter of discharge	5 in.
Diameter of steam pipe	2 in.
Diameter of exhaust	4 in.
Diameter of steam drips	½ in.
Diameter of water drains	½ in.
Discharge head, lb. per sq. in.	175
Temperature of feed water	200
Pounds of water per minute	
Pounds of water per 24 hours	
Type of piston packing	
Kind of rod packing	soft
Size of rod	⅝ in.

Specification Data—Soot Blowers

Make of blower	Diarmond
Cost of installation	$720.00
Date installed	June, 1917
Type	Model "G," Revolving
Number of calorized units	3
Number of plain units	3
Type of header	Vertical
Diameter of header	2 in.
Diameter of risers	1½ in.
Make of valves	Hancock
Diameter of drains	½ in.
Location of units	see blueprint 2-395 & 2-405
Diameter of nozzles	5/16 in.
Type of nozzle	Venturi

The above records, while apparently very complete, could probably be supplemented with additional data. It has seemed desirable to give them in detail in order to illustrate the importance of maintaining such specifications as it must be evident from an examination of them that if such records are maintained on file a great deal of valuable time can be saved when it is necessary to look up points in connection with any of the equipment. Among the records of this sort to be kept are the number and type of the various motors installed about the plant; the number and size of lights; the dimensions of buildings to be heated; the amount of radiation installed for heating purposes; the number and diameter of live steam mains leading to points where steam is used in manufacturing processes, etc.

Operational Records

In previous articles we have discussed the use and the value of various measuring and recording instruments in the power plant. The records which these instruments give bear the same relation to the power plant as the accounting system does to manufacturing operations of the main plant. It is only by tabulating and studying them that improvements in economy can be effected.

Unfortunately, it is not as easy to lay out a system of records for a power plant with the same facility with which an accounting system can be laid out for a business. Everything depends upon the size of the plant and the conditions under which it operates.

With large central stations, permanent recording instruments can be installed, showing the steam flow, flue gas temperatures, CO_2, pounds of coal per minute, pounds of feed-water per minute, etc. With such records, it is extremely easy to detect errors in operational methods, and correct them.

With a small plant, however, the cost of these devices may be prohibitive. Generally speaking, however, the small power plants of the country are inadequately supplied with measuring and recording devices, and every effort should be made to rectify this condition. Improvements in operating conditions are only possible with fairly accurate knowledge of the actual conditions obtaining in the plant.

Therefore, if you are the owner or manager of a medium-sized or small power plant, see that your operating men are supplied with at least some of the fundamental instruments.

Even if they only take CO_2 and flue temperature records at intervals, they will do better work and will cut the costs of production because the instrument will tell them where "they are at."

It is very stimulating to have performance records before them, but these are of no value if they are filed without being studied. The oftener readings are taken the better. Monthly and yearly averages are not enough Daily, and even hourly, records are absolutely essential for maximum economy. Only by an intelligent analysis of daily records may the various losses be reduced to a minimum.

Load and Demand Factors

The average daily, monthly and yearly load and demand factors of every power plant should be plotted and posted where they may be conveniently studied by the operating force. The load factor is, of course, the ratio of the actual output for the period covered to the rated capacity. In order to avoid

any confusion regarding the term "rated capacity," it should be taken as the maximum load which the prime mover can sustain continuously for twenty-four hours every day without overheating. To secure the greatest return on the investment in the power equipment, the thing desired in any power plant is a high load factor, not only daily, but weekly, monthly and yearly. If this is secured, all the factors which go to make up the cost of power should be operating at maximum economy. Low average loads and high peak loads and seasonal fluctuation in power requirements, necessitate large pieces of equipment which are but little used and therefore greatly increase the fixed charges.

Where conditions of fluctuating load exist in a manufacturing plant it will often prove economical to operate only as many boilers and prime movers as may take care of the normal steady load, and to buy additional power required from the central station. This condition should be carefully studied by every operator of isolated plants.

The demand factor is the ratio of the maximum demand of all the various types of equipment to the connected load. One of the commonest mistakes made in industrial plant practices is to overestimate the maximum demands resulting from the probable use of a large part of the equipment at the same time.

Thus, if a plant has a 1,000 h.p. of motors installed, the management might assume that a prime mover capable of supplying current to operate 800 to 900, or even 1,000 h.p. would be required, whereas a 60 per cent. load factor which would only require a prime mover capable of developing 600 h.p. is the general average in industrial plants. Of course, conditions vary in different plants, but before installing a large number of boilers and prime movers to supply theoretical demands, actual demand factors for the plant should be determined as accurately as possible. This is an extremely important point as it is very uneconomical to assume that because certain h.p. of motors is installed that an equal number of prime movers is required.

Cost of Power

In two power plants, built to exactly the same specifications, that is, with the same number and make of boilers, prime movers, etc., the cost of power may, and does, vary considerably. Every plant requires individual study. Among the factors to be taken into consideration are size of plant, load factor, load variations, ratio of maximum load to economical full load, number of hours a day the plant operates, cost of fuel, oil, waste, repairs, labor, insurance, taxes, maintenance, depreciation, management, and overhead.

In determining the costs in any plant, the first items to be arrived at are the fixed charges, that is, those items of expense which do not expand and contract with the output. Insurance, taxes, interest, and to a certain extent depreciation and maintenance go on whether the plant is in operation 1 per cent. or 100 per cent. of the time. To a large extent, labor is a fixed charge, since practically the same number of men are required if the plant is operating at 50 per cent. capacity as at 100 per cent.

In studying the question of fixed charges with respect to a power plant, we are invariably driven back to a consideration of the load factor. This is true, because the higher the load the greater the operating charges, which cover such items as fuel, oil, etc., will be.

With a low-load factor, fixed charges may easily be the dominating item of expense, and any additional investment in the plant should be avoided. With a high-load factor, economy of operation is of paramount importance, and the equipment which will secure greatest operating efficiency may prove an extremely profitable investment.

Depreciation

Depreciation is an extremely difficult matter to handle correctly in any power plant.

We may as well admit frankly that it is almost impossible to estimate, with any degree of accuracy, the life of any piece of equipment.

Among the factors which enter into the question of depreciation, one of the most important is obsolescence. With the remarkable mechanical developments of the present age and the rapid growth of our industrial plants, we never know when this factor is likely to appear.

When it does come up it is apt to call for the scrapping of numerous pieces of equipment which are in splendid running order but which it is no longer profitable to operate because more economical machines are available.

Inadequacy is another factor resulting frequently from expansion of plants, community growth, etc. In addition to the two factors just mentioned, the possibility of destruction, due to fires, flood, etc., are to be considered.

The natural wear and tear on equipment may be estimated within reasonable limits.

It is safe to assume, for instance, that a brick or concrete building will last 40 years; a water-tube boiler, 25 years; a high-speed engine, 20 years; a generator, 20 years; condensers, heaters, pumps, etc., 20 years; motors, 15 years; conveyors, 15 years, etc. Then, if desired, a proportionate amount of depreciation can be charged off each year. This is the method generally used.

It can hardly be termed satisfactory or accurate. In making this statement we must admit the difficulty of substituting a better method.

Personal observation, however, may indicate to the individual plant manager points where he can make more accurate allowance for depreciation without a flat charge of a certain percentage each year.

For instance, the moment a piece of equipment is put into service it becomes a used article, and as such, probably commands not to exceed 60 per cent. of the value of a new article. After this initial 40 per cent. depreciation there is a period of several years when the value of the equipment will decline slowly. After that there is apt to be another rapid fall as new and improved equipment comes on the market, so that at the end of five years it is worth only 20 or 30 per cent. of its original cost.

This 20 or 30 per cent. valuation, however, is quite likely to be maintained for a considerable period of time, even if new and highly-improved equipment may be obtained on the market. At the end, say, of six years from the date of the original instalment of the equipment, it is quite possible that if the depreciation on the equipment shall have been so charged off the books of the company that it represents only 20 or 30 per cent. of the original valuation, and it will be more economical to operate the old equipment than to instal new, whereas if the old equipment was held at 70 per cent of its original valuation it might be more economical to scrap the old equipment and replace it with the new and improved type.

The method to be employed in charging off depreciation is a matter for individual study, and is largely dependent upon the earning power of the power plant.

The point cannot be emphasized too strongly, however, that in the present age the chances are all in favor of obsolescence overtaking a piece of equipment long before the expiration of its natural life.

The "Railway Review" says that in the Dalen System of acetylene gas lighting for railway cars, inverted incandescent gas mantles are used, but instead of the air necessary for combustion being added in a bunsen mixture at the burner itself there is an automatic mixing device attached to the storage tanks beneath the car floor. This arrangement renders the completeness of combustion independent of the rate of combustion at the burner which can thus be satisfactorily run either fully or partly turned on. Owing to the constant pressure, low and high power lights can be operated off the same system. Flashing, causing the destruction of mantles, is quite done away with and the atmosphere is kept much purer.

The Southern California Edison Co., of Los Angeles, has carried out a series of experiments on rock removal for tunnel projects, using alternating and direct-current arcs and various types of gas blowpipes. From a cost point of view the best three-phase run cost one farthing per pound of rock removed. The single-phase arc did not show quite such good results. With direct current the cost worked out to one-eighth of a penny per pound of rock removed. Experiments were also made with various types of welding and cutting blowpipes using oxy-acetylene, oxy-hydrogen, and oxygen with natural gas. The oxy-acetylene flame concentrates the heat best at the tip of the white cone. When moved across the rock at the proper speed, the stone clipped off readily because of uneven expansion, but when the entire flame was virtually a neutral flame the rock became molten and the surface glassy and impenetrable. Assuming oxygen to be as cheap as one-eighth of a penny per cubic foot, the cost of oxygen alone was greater than five-eighths of a penny per pound of rock removed.

A Third Class Certificate Requires—

A Knowledge of the Engineering Subjects Given Below Should Enable Any Engineer to Pass Satisfactorily the Examinations Set for the Third Class Certificate

THE applicant for a third-class certificate must hold a fourth-class certificate and should, of course, be familiar with all the knowledge required for the successful passing of the fourth-class examination.

The requirements which he will otherwise have to meet insofar as training and experience are concerned may be summarized as follows: He must be at least 21 years of age and must be able to furnish evidence that he has had at least two years' experience as fireman, oiler, or assistant to the engineer. Note that any one of the three last named positions held for a period of two years will enable him to try the examination. Testimonials must be produced as to length of service, and they must be signed by his employer, in the case of shop time, and by his employer or chief engineer in the case of engineer's or firemen's time. These testimonials must state the kind of work the candidate has been employed on, and for how long; and give evidence as to his experience, sobriety and general good conduct for at least twelve months preceding the date of application for examination.

Sixty per cent. of the marks awarded for the correct answering of the questions on the examination paper are necessary for success, and while the examination is a written one, the applicant may be required to answer questions, asked him in an interview, regarding his knowledge of the operation of a steam plant.

The applicant for a third class certificate should have a good grounding in arithmetic. This includes addition, subtraction, multiplication and division. A knowledge of decimal fractions is also desirable but not absolutely essential. He should know how to square a number and how to find the square root when the number is given.

He should have an elementary knowledge of combustion, that is he should know that certain substances unite with the oxygen of the air and give off heat in doing so. He should know that carbon burns to either of two gases—carbon monoxide (CO). or carbon dioxide (CO_2)—and that only when burned to the latter is the heat value of the fuel fully utilized. He should, in this connection, know that an insufficient supply of air will result in the production of the former gas and that while excess air usually results in complete combustion, it also wastes fuel through its cooling effect. It should also be known that the gas hydrogen exists in fuels, combined with the carbon and that when this element combines with oxygen water is formed and heat is given off.

An elementary knowledge of heat should be possessed by the applicant. He should know how temperature is measured and should be able to give intelligent answers regarding the Fahrenheit thermometer. He should also know how heat, in contradistinction to temperature, is measured, and should in this connection be familiar with the British thermal unit (B.T.U.). That is, he should know that it is the amount of heat required to raise the temperature of one pound of water one degree Fahrenheit. He should also know that water boils at certain definite pressures depending upon the pressure to which it is subjected. This does not mean that he should be familiar with the exact figures beyond the one that it boils at 212/ Fahr. when under atmospheric pressure. He should also know that while the temperature remains stationary heat is required to evaporate the steam and that this heat, a definite amount per pound of water evaporated at various pressures, is commonly called the latent heat of evaporation.

A knowledge of the manner in which a steam engine works is necessary. This includes an elementary knowledge of steam working expansively, and how it does work in its expansion. He should be familiar with the general physical properties of materials with which he comes into contact in his daily work. This does not mean the memorizing of tables of tensile strength, etc. Nor does it mean ability to figure out the strength of shafts, beams, etc., but only a working knowledge of materials such as is desirable in their general use. He should be familiar in a general way with these materials, such as iron and steel, lead, copper, brass and bronze, brick and firebrick, wood and concrete.

The regulations respecting the Act specify that questions will be asked "Relating to the different kinds and manners of constructing boilers to generate steam, including the strength of materials used in constructing the same." Any questions asked relative to the last part of the above extract will necessarily have to be of a simple nature, and, needless to say, will not embrace boiler design in its usual meaning.

Hydraulics is mentioned as being one of the subjects upon which the applicant will be examined. The subject of hydraulics is a very wide one but the portion of it with which we are concerned is relatively narrow and simple. Simple facts relating to pressure and head, and friction in connection with the flow of liquids or gases through pipes and fittings will be about all that is required. An understanding of what head and pressure are is necessary, and a knowledge of the fact that flow produces friction is equally desirable. Fittings are mentioned, since their presence in a pipe-line causes friction and a loss of head or pressure when flow occurs.

In all that has been mentioned above and in that which follows it must be understood that the information given is supplementary insofar as the third class applicant is concerned, to that given for the fourth class examination, and published in POWER HOUSE for Oct. 5, 1919. That is to say, the applicant may find on his paper questions relating to information which a fourth class engineer should possess and which he also should have a complete knowledge of.

He should be familiar with the construction, insofar as familiarity with names and the shapes of the parts are concerned, of a steam boiler, with its manhole and handholes, shell, dome, staying, etc. That is, he should be able to describe them accurately and to describe their functions.

He should also be familiar with the maintenance of these various parts and of the boiler as a whole and should be able to describe how to go about minor repairs. Superheaters will also come under consideration, and he should have a similar knowledge of their construction and maintenance.

Feed water equipment is a necessary part of any boiler room and an important one. In consequence the applicant will be liable to be asked concerning feed water heaters, pumping equipment and piping with its valves. The proper method of operating any of this equipment is important as is also the question of repairs and emergency breakdown service.

Feed-water heaters will include both the open and closed types. The pumping equipment will embrace the various forms of steam pumps and injectors while the piping and valves are self-explanatory.

The blow-off is an important feature and the best construction and arrangement should be known together with the proper method of using it and the means to be taken to keep both blow-off valves and piping in proper working order.

The third class applicant should have a sound knowledge of the safety valve. He need not know how it is proportioned and what its proper size should be, but he should know how it is constructed, what its function is, how to operate it and how to maintain it in a proper working condition. In connection with its construction he should be able to describe accurately the various types such as ball and lever, spring loaded and dead weight.

The water gauge and try-cocks also come in for consideration, and he should possess a similar amount of information to that required for the fourth class certificate.

He should also be familiar with the pressure gauge and its syphon, and should understand how to care for it and how to read it.

The third class applicant should be familiar with the various methods of coal storage and supply, and it would be of advantage to him if he were acquainted with the various types of conveyors, both for coal and ash handling, and it would also be of advantage if he were possessed of such a knowledge of their construction as would enable him to intelligently care for them.

He should know how to store coal properly in open piles and in bunkers, and in connection with the storage of coal he should know that coal is liable to spontaneous combustion. He should be able to give intelligent answers relative to the prevention of this occurrence and to its control and mastering. He should be acquainted with the best methods of firing and the proper way to fire different fuels.

He should be familiar with the various parts of a boiler setting and should know the construction, function and proper method of operation and maintenance of the various parts, particularly those having to do with combustion. He need not know how grate surface enters into the capacity of the boiler for generating steam, but he should know how to fire properly and keep both grates and other parts of the setting in working order.

He should know how to regulate the air supply.

The third class certificate is the first one in which the applicant is required to know anything about engines. Since the upper limit of the boiler horse-power which will be placed under his charge, unless he is given this grade automatically when the act comes into force, will be 150 horse-power, the details of the larger sizes of engines will be of little interest to him. What he should know will embrace the more common types of engines seen in power houses up to 150 boiler horse-power.

He should have a good knowledge of the construction and functions of the various parts of a steam engine, such as the cylinder, piston, piston rod, crosshead and connecting rod. He need not know how these are designed for this is properly a function of the designing engineer, but he should know how to properly care for an engine under his charge, how to lubricate it, how to pack the glands and how to make necessary minor repairs. The proper adjustment of loose or tight bearings also should be known.

He should know something about valves and their operation. He need not be familiar with valve diagrams but he should know what lap and lead are and how the position of the eccentric relative to the crank affects the lead of the valve. If he understands what functions these various questions play in the running of the engine, so much the better.

The action of the steam in the cylinder naturally enters into this phase of his knowledge and accordingly he should know what goes on in the cylinder.

Governors are a necessary part of any engine and it is a vital part of the engineer's knowledge that he should understand what they are for and how they operate, in an elementary way. Their proper maintenance in a safe operating condition should not be overlooked.

The condenser is a part of the prime mover element in many power plants and for this reason the third class engineer should have a general knowledge of their construction, their function and their proper operation. The surface and jet pipes are the two principal types used in Ontario, but if he knows something about the syphon or barometric type, so much the better.

Piping and accessories enter into the construction of any power plant and in addition to knowing how to look after piping and the various accessories the third class engineer should know how such accessories as expansion devices, valves, traps and separators function, and he should know how to maintain them at their proper working efficiency and how to effect repairs.

He should know what heat insulation is for, how it functions and how to take reasonable precautions to keep it in order.

Hydraulics is mentioned in the regulations respecting the Act as one of the subjects with which the third class engineer will be required to be conversant, and for the purposes of examination this will probably be confined largely to the subject of pumps and pumping machinery. The engineer should have a good working knowledge of the more common types and should be able to describe how they function. He should also be able to tell how to get them into proper adjustment and how to repair them. The more simple facts relating to the theory of hydraulics, such as head and pressure, friction loss in pipes and fittings, etc., also should be known.

Distribution of Boiler Room Load

By JOSEPH HARRINGTON in "Power Notes"

ONE of the characteristics of the steam boiler is that it has a certain capacity corresponding to its best efficiency. With certain types of firing the capacity-efficiency curve has a very sharp peak, which means that the range of capacity at which the boiler can operate efficiently is very limited. When operating at less or more than this given capacity, efficiency drops off very rapidly. Without question, a flat capacity-efficiency curve is something much to be desired; and the best forms of stokers flatten out this curve very materially as compared with others, and with hand-firing.

It is a matter which astonishes the firemen when steam flow meters are installed, to see how differently the various units are operating. One boiler will have its flow meter hand clear around on the peg, and the next boiler, without an appreciably different-looking fire, will be loafing along below rating. In an hour or two, this conditions may be reversed; and if this condition persists, there is a distinct waste of coal at all times.

It is up to the careful operator, therefore, to take such steps as will assure him that the various boilers in his plant are carrying about the same load, which naturally should be somewhat within range of the most efficient operation. If the plant is large enough to warrant it, one or more boilers should be taken off the line when the load gets down to a point where the average is less than the economical capacity for the unit. Too often do we see every boiler kept in service in little more than banked condition, and operating at 30 or 40 per cent. efficiency. It would be far better to run half the number of boilers at twice the rating at an efficiency of 60 or 70 per cent. Standby losses in this case are less than the operating losses.

Now the question instantly arises as to how the operator can tell what load the various units are carrying; and the answer is only by some indicator which shows either the amount of water going into the boiler or the amount of steam coming from it. From my standpoint, either method is satisfactory; but it must be determined for each individual boiler. Only in this way can one tell what is doing. Even the indications of draft are not entirely satisfactory, for the simple reason that a draft reading is an indirect indication. When carefully worked out, with gages to show the loss through the fire and through the boiler, and checked against coal and water rates, the draft indications will show very closely the condition of the fire and the rate of steaming; but there is certainly an advantage in an absolutely direct indication.

The Horse Power Rating of a Boiler

SOME misunderstanding seems to have arisen relative to the horsepower rating of boilers under the Ontario act grading certificates. The Act defines a boiler horse-power as follows: The equivalent to the evaporation of 34 lbs. of water per hour from and at 212° F., 15 sq. ft. heating surface for return tubular boilers, 12 sq. ft. heating surface for locomotive type boilers, and 10 sq. ft. heating surface for water tube boilers. The figure 34 lbs. specified in the act, in the first place is not strictly correct as the rate of evaporation now fixed by the A.S.M.E. as standard for one horse-power is 34½ lbs. of water evaporated from and at 212° F. per hour.

Any figure giving the number of square feet of heating surface per horse-power can only be an approximation of the supposed capacity of the boiler for doing work since it does not take into consideration the grate surface and the fuel burned, both of which, of course, have a very important influence on the evaporative capacity of the boiler.

The figure of 10 sq. ft. per horse-power has long been used by manufacturers and others as has also the figure 12 sq. ft. That of 15 sq. ft. for horizontal return tubular boilers mentioned in the Act is the figure which will be used for the purpose of administering the Act and the manufacturers' rating, no matter what it is, will not necessarily count unless it happens to be on the same basis.

If a manufacturer rates his boilers on a basis of 10 sq. ft. per boiler horsepower and an engineer has a plant of 300 boiler horse-power under him, determined on the above rating, for the purpose of grading under the act, it will only be of $300 \div 15 \times 10 = 200$ boiler horse-power capacity.

It must be remembered that the term boiler horse-power, in speaking of heating surface, is only relative and of no fixed value, unlike the mechanical horse-power. On the other hand, the rating of a boiler in terms of its evaporative capacity and on a basis of 34½ lbs. from and at 212° F. is the more sensible and logical method, and has some basis of scientific logic behind it.

System in the Power Plant

HOW often do you or your men test the safety valves—once each shift, one a day or once in every little while, say a week or two? And how often are other vital points around the power plant inspected, or how often are the fires drawn and the boilers cleaned down and inspected?. In short have you any systematic method of going about your duties while on shift or directing others in the performance of routine work?

System is a wonderful smoother of the rough spots in our everyday world, and while it acts as a lubricant it brings in returns measurable in dollars and cents.

It is for this reason that business demands system in the performance of the routine work of accounting and management and it is for the saving effected in time and money, and for the results achieved, that the engineer may well inject a bit of system serum into the management of his power plant.

The Future of Stationary Engineering

MUCH speculation is frequently indulged in over the prospects of Hydro-Electric power completely ousting the small steam plant devoted to the generation of power. This tendency, it is true, has been very marked in Ontario at least during the past decade and the boiler in many cases has been relegated to the position of a heating device and not one of the links in the generation of power from coal through the medium of steam.

To say this change has not affected the engineer's status would be incorrect. It has, and in many cases to the engineer's disadvantage. This should not be the case and the remedy lies in his own hands; education and the keeping abreast of developments in the engineering field will not only enable him to hold his own, but will enable him to be of more value than before.

Stationary engineering embraces an ever-widening range of subjects and the engineer of to-day must know much more than engine and boiler management. Electrical engineering and refrigeration are two subjects which the engineer will have to be acquainted with to an ever-increasing degree.

The Old Family Group

IT is not pleasin' unto me, in fact, it grieves me sore, to see some things a-passin' we loved in days of yore—folks seem to be all changed about in this here awful age, a-tearin' here and there, by gum, in one mad, giddy rage.

It causes me to shed a tear the way they've put the boots to them there photos that we called the old-time family groups.

I love to gaze upon them things, their faces and their gowns—their countenance set for the pose, all freed from grins and frowns. They set there lookin' back at me, that group took years ago, poor things not knowin' that them groups was out-of-date and slow.

Why, when they go out nowadays to get their likeness took, folks try to look like some front page from out a "movie" book. The women get a yard or two of fly-nets round their bones, by far too flimsy and too thin to venture from their homes. They gaze up at the rafters, 'cause the photo man says so; they're dressed in some partic'lar style with no place much to go. And when their friends grab off the prints they snicker and they grin; the things they say they constitute a high crime and a sin. But to their faces they cry out, "Oh, excellent! Oh, fine! Prunella, dear, your profile shows a snout that is divine!"

Likewise when Dad goes out to sit before the camera man, he has to have an egg shampoo, also a meal of bran—he looks as great men look each day, as though he'd like to feel just how 'twould be before the night to swing a million deal. Why, if Dad pulled that picture face when trudgin' 'bout the house, we'd swear he was recoverin' slow from some hard cider souse.

Of course, we've got to be in style like all the other folks; it aint no use in laggin' like a lot of has-been blokes. But all the same, them family groups look powerful good to me, when Dad was young and handsome and Maw was twenty-three. I like to look at them, I do, just settin' there, by heck, without no care or worries a-campin' on their neck. No cheese cloth wrapped about Maw's chest, nor yet upon Dad's jaw is fixed an attitude to state he's gone and bust the law.

Ah, yes, I know it's out-of-date to have a family group, but for them photos nowadays I don't care one durned whoop. Lead back the good old family group with pleasant face and sweet, with palm trees rustlin' in the rear and foostools 'round their feet.—ARK.

A Real Imagination

WE are indebted to "The Locomotive" for bringing this gem of pure imaginative effort to light. It is supposed that it was written by a member of the air service at Scott Field to his father and was found near the Southern Railroad Station.

"I have been appointed Mess Sergeant of the Flying Detachment, Scott Field, and to show of what my work consists, I will give some few examples of our tasks and efficiency.

"The kitchen range is 500 feet wide and 3,000 feet long, takes 27 experienced firemen to keep the heat at the necessary temperature. 400 cooks on duty at all times, 1,000 mechanical stokers for kitchen police and 1,000 assistant kitchen police who look after the stokers.

"Two hundred washing machines are used for washing the potatoes. 27 pile drivers mash them, 14 steam shovels shovel eggshells away from the kitchen door. Twenty-two Liberty motors are used in the coffee mills. Dirty dishes are hauled out to 11 blast furnaces, as the dishes are all paper and are burned after each meal. Hot cakes are mixed with 19 concrete mixers and 46 men with bacon rinds attached to their feet continually skate over the large griddle to keep it greased.

"Soup is made in an artificial lake, which keeps 34 dump trucks busy hauling the necessary ingredients. Cooks use steel boats and are dressed in asbestos clothing. Every few minutes they row to the centre of the soup lake and drop depth bombs to properly stir the mixture. Sixty-seven fire engines are used to pump soup to the 954 tables. Bread is cut by 11 high-powered band saws. A perforated endless conveyor properly salts and peppers the victuals. Twenty large street sprinklers are used to place syrup on cakes. Coffee is made in a 600-gallon tank and pumped to the tables through pipes by 17 centrifugal pumps. Ten five-ton rollers are used to roll the batter. To save labor and cost six-inch mains have been installed from 20 of the country's largest dairies for the supplying of milk.

"Radio telephones are used by the Mess Sergeant, who also uses a motor cycle in travelling around the dining hall and kitchen. All cooks wear gas masks. Ford trucks haul the silverware. Now, dear father, you can see just what I have to do and why I do not desire to quit the army."

The Tunnel Will Be Built

FOR years engineers have talked of the day when the tunnel would be completed between England and France. The world in general has not been much interested, probably because the world in general never thought such a thing practicable.

But work is going to start—start from both sides, the French and English Governments to find an equal share of the money and provide an equal share of the men.

Then it will be possible to take a train at London for Constantinople, for any European capital. Through the tunnel the line will be run by electric power. This will prevent trouble with engine fumes, which was one of the serious objections to the long tunnel through the Alps.

Forty-five minutes will be occupied in going through the Channel tunnel. Passengers, in fact, will pass through the tunnel almost without realizing they are passing under stormy Straits.

The tunnel will be about thirty miles long. It will not be exactly in a straight line. Beginning at a spot two or three miles on the island side of Dover, it will follow the gray chalk bed of the Channel, which is impervious to water and suitable for tunnel construction, and come out at a point between Calais and Boulogne, near the village of Marquise.

There will be, as on the London underground railways, two distinct tubes. Below them, about nine feet in diameter, will be a drainage tunnel. The whole work will take five years to complete and will employ 1,200 men on each side.

The French, who are proud of their share in the tunnel, will do half the work and find half the money. There is bound to be much friendly rivalry between the two sections of workers as to which will go ahead the faster.

According to exact calculations of the engineers, the French and British workers, who will begin construction of the tunnel thirty miles apart, will meet within an inch or two of the centre of the tunnel.

For a long time the waste steam from steam-engines has been turned to good account, but there have been difficulties in the way of using the exhaust gases from a gas-engine as they readily attack the metal of the conduits. However, the difficulty is being overcome, for a New Jersey candy factory has an installation in connection with a sixty horsepower engine which is used to heat the factory. The gases pass through an economizer made of cast-iron, with the passages to the different sections staggered so that all parts are heated for the whole length. Water circulates in jackets surrounding the gas passages.

* * * *

THE assurance of Washington that Canada will not be discriminated against in the matter of coal shows more spirit than the threat to cut Canadian power off United States when it was short here.

NEW POWER PLANT EQUIPMENT

DEAD GAS POCKETS FOR PROTECTING SOOT CLEANER ELEMENTS

IN connection with their research and development work, the engineers of the Vulcan Soot Cleaner Co., Du Bois, Pa., have brought to light some valuable and interesting information regarding the protection of soot cleaner elements by means of so-called "dead gas pockets."

Inasmuch as the temperature of combustion in a boiler furnace frequently reaches 2500°F., it is evident that soot cleaner elements cannot be placed within the immediate zone of this high temperature. Protection of some kind against both convection and radiation is necessary, especialy in steep tube boilers such as the Stirling, Erie City, Badenhausen, Connelly, Ladd, etc., which require cleaner elements at the bottom and top of the first pass. The temperature at the bottom and top of the first pass is usually high, whereas in the second and third pass it drops to a degree that does not influence the strength or properties of wrought iron or steel.

FIG. 1.

As applied to horizontal water tube boilers the temperature problem is seldom a serious one because it is the usual practice to place the soot cleaner elements at the top of the tube bank where the temperature seldom if ever reaches 1000°F., a temperature that does not affect cast iron sheaths.

To fully protect the soot cleaner elements in steep tube boilers, a patented deflecting baffle title, or row of fire brick forming a pocket in which the element is operated is placed at the bottom of the first pass as shown in Fig. 1. This pocket eliminates the direct scrubbing action of the hot gases. Space is allowed at the bottom of this baffle through which soot and ash will drop during the cleaning process. The cast iron sheathing used for further covering and protecting this element is clearly illustrated in Fig. 2.

At the top of the first pass is another patented dead gas pocket in which is located the second soot cleaner element. This element, also, is further protected by means of the special cast iron sheathing, shown in Fig. 3. This second element rests upon the circulating tubes close to the front drum as shown in Fig. 4. Contact with the comparatively cool tubes asists greatly in maintaining the element at a safe temperature.

By arching the baffle tile over the circulating tubes as shown, the hat gases, in their natural flow, do not come into direct contact with the element. The elements in both instances are placed in strategic and commanding positions, making it possible to clean easily what has heretofore been the most difficult and the most important portion of the boiler—the first pass. It is well known that in the steep tube type of boiler, most of the steam is generated in this pass, hence the importance of keeping the first pass well cleaned.

In boilers of this type, where the tubes are arranged in squares, perpendicular nozzles are used, as shown in Figs. 2 and 4. That is, the nozzle makes a right angle with the axis of the elment, hence the jet is directed between the tubes. With a nozzle blowing into every space, rotation of each element in Figs. 1 and 2 through approximately 90° thoroughly cleans the entire bank of tubes.

In the Vogt boiler there is a departure from conventional horizontal water tube boiler design, making it necessary to place two of the elements closer to the high temperature zone, as illustrated in Fig. 5. Hence the element No. 1, which is closest to the hot burning gases and glowing fuel bed, is protected by a dead gas pocket as well as by cast iron sheaths. The next element reached by the hot gases is protected by a straight diagonal baffle (also visible in Fig. 5), forming a second dead gas pocket. The third element reached is protected by a

FIG. 2.

FIG. 4.

dead gas pocket in a manner similar to element No. 1. By the time the gases reach element No. 4 the temperature of the gases has dropped sufficiently so that a dead gas pocket is not necessary to cover the element with cast iron sheaths.

Experience has proved that burned furnace gases are non-oxidizing, hence there is little, if any, hazard in exposing bare elements to the low temperature gases. The high temperature problem is, as a rule, of greater importance than the corrosion problem, but this has been effectively solved by these investigators by means of combined dead gas pocket protection, cast iron sheaths, and contact with the comparatively cool boiler tubes.

LUBRICATING AMMONIA COMPRESSORS

To perform its functions properly, a lubricating oil should have body sufficient to keep bearing surfaces apart; should reduce friction to a minimum; should remain fluid at the lowest temperatures to be met in service; should not decompose and form deposits that will gum up the machinery; should have no ingredients which can corrode or pit metal, and should have flash point high enough to insure against the presence of volatile constituents.

To avoid vaporizing too quickly under the high compression heat in an ammonia compressor cylinder, a lubricant must have a good flash, say, 325 deg. F., and as some oil in vapor form is

FIG. 3.

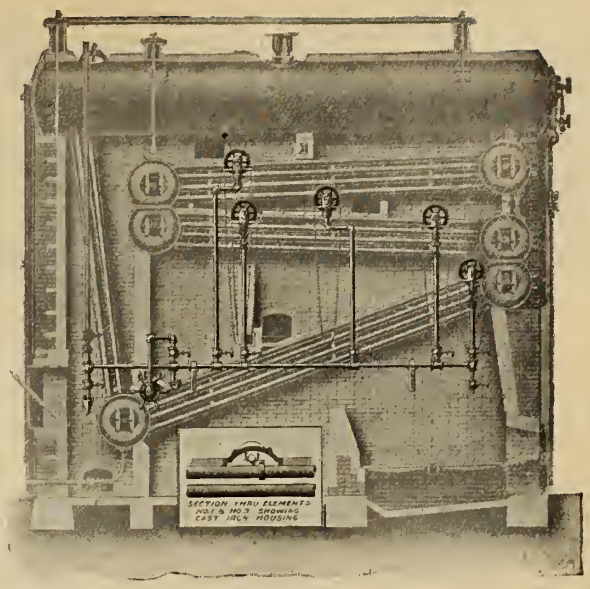

FIG. 5.

likely to be carried into condenser pipes with the ammonia gas, the cold test should be low enough so that the lubricant will not solidify in the piping and coils—5 to 10 deg. F. If it is carried on through with the liquid ammonia, it can be taken out by an oil trap, placed ahead of the liquid receiver and at the lowest point in the expansion and condenser coils. Such a trap may be made of a piece of 4-in. piping, 2 ft. long, with a draw-off connection at the bottom.

If the lubricating oil gets into the condenser coils and stays there, it can be loosened by cutting off the water from one stand at a time, allowing the coil to become hot, so that the oil is thinned and will run off into the oil trap.

Oil carried over, and collecting in the condenser and expansion coils, is a source of lost capacity, and is frequently due to locating the oil separator too close to the compressor discharge, where the gases are hot and the oil mostly in vapor form. Placing the separator near the condenser gives time for the gases to cool somewhat before reaching it, so that the oil is partly condensed and is more readily separated.

All oil used for the compressor cylinder should be measured and a record kept. Any unusual increase in the amount fed should lead to an immediate investigation to prevent filling of the system.

As hot ammonia gas has a bad effect on stuffing box packing, a liberal supply of oil should be applied to the piston rod in the stuffing box to reduce the chance for overheating.

Discoloration in the ice is not always due to oil. Two cases were mentioned in the discussion, one where firebrick was used to fill an open heater in which there were no flow pans, and the mineral matter from the brick carried over into the ice; the other where rust from a fore cooler caused the trouble, which was remedied by painting the inside of the fore cooler.—From a paper and discussion, Nat. Ass'n. Prac. Refrig. Engrs. in "Compressed Air."

SOME CONDENSED ADVICE ON COMPRESSED LUBRICATION

Explosions in air compressors and receivers occur with sufficient frequency to demand careful attention. The majority of such explosions are undoubtedly due, either directly or indirectly, to the lubricating oil used in the air cylinders. Poor working conditions of the compressor, such as leaking valves, hot and dirty inlet air, insufficient cooling water, carbon deposit in cylinder or connections, and high speeds of poorly designed compressors, all assist in producing dangerously high temperatures of the compressed air. These high temperatures are sufficient to ignite the volatile constituents of the lubricating oil, and produce violent explosions.

The Massachusetts Boiler Board recommends the following rules:

(a) Keep the temperature of the compressed air, during compression, as low as possible.

(b) Keep the piston and valves tight, and in good working condition.

(c) Take the inlet air from as cool and clean location as practicable.

(d) Use plenty of cold water, from a source which is not liable to fail, and have it visible at discharge from cylinders or coolers.

(e) Do not use kerosene or other volatile substances in the cylinder, tanks or any connections.

(f) Use mechanical or sight feed oilers for the compressor cylinder.

(g) Use the least amount practicable of the best air cylinder oil. Air cylinders require much less oil than steam cylinders.

(h) Keep the cylinder, tanks and connections as free from carbon, accumulated oil and deposits as practicable.

(i) A good cylinder oil is one which lubricates well, leaves little or no deposit, is the least volatile at high temperatures, and has a high flash point.—"Compressed Air."

ABERTHAW CONSTRUCTION CO. TAKES UP AGAIN ITS STUDY OF THE EFFECT OF VIBRATION IN STRUCTURES

Four years ago the Aberthaw Construction Co. started an investigation on the vibration of buildings, particularly manufacturing buildings. The study was intended to cover not only the causes of vibration, but also the effects on the structure, on the machinery installed, and on the quantity and quality of production.

A preliminary report was published in the fall of 1916, but our entry into the war and the many new problems which that brought, put a summary stop to the work. It is now being taken up again with the idea of following through to a point where a complete report can be published. The Aberthaw Construction Co. will therefore be glad to have engineers, manufacturers, and others having knowledge of the subject, or having had specific experiences which would throw light on any of its phases, communicate with the company at 27 School Street, Boston.

The previous work on this problem showed a wide diversity of opinion on some of its angles. It also developed that there is very little quantitative information extant which can be relied upon as giving authoritative data. It is particularly desired, therefore, that information of this character, however limited in its application, may be made available for the study.

Privy Council Awards Share.—The proceeds of the sale of the steamer "Storstad," which sunk the Empress of Ireland, will be shared by the C.P.R. The Canadian Supreme Court gave the preference to the passengers, but the Privy Council reversed the decision.

The Operators' Point of View

GRADED CERTIFICATE CORRESPONDENCE

Editor, POWER HOUSE:

The letter by "Chief" on page 527, POWER HOUSE, November 20, contains the sentiment of most of the old engineers. An illustration of my own case will show up the injustice as explained in part by "Chief." I have been an engineer for thirty years, have been 1st engineer of 500 h.p. plant and larger plants for eighteen years, and am now 1st in a 500 h.p. plant. I held 1st class papers with the Ontario Association of Stationary Engineers, and still have the last certificate, issued in 1907. I have taken two correspondence courses in engineering from a well-known school.

I believe I am a first-class stationary engineer in the fullest meaning of the word. I have sent letters on engineering subjects to POWER HOUSE since its first issue, and have had my letters printed by other engineering journals for the past twenty-five years.

With all the foregoing experience and study I am positive that I could not now, write such examination question answers as I had to do in the past to secure 1st class papers. The principal reason that would prevent me passing such an examination is my memory. When I was younger I could remember hundreds of rules without difficulty; now, however, I am compelled to refer to my text books very often to feel certain I have the problem worked out right. I understand the rules and can work out any possible engineering problem with the assistance of the text books.

Men having such experience and knowledge such as I possess should receive 1st class papers without having to pass a difficult memory test. We are willing to pass a knowledge test. The statement made by "Chief" about the mental abilities of engineers over fifty years of age are right in my case, as the new law is worded I will have to do with 2nd class papers and drop back into small plants. Should I make a change and still be 1st engineer, this will be so even if I am as good or better, as an engineer, than the youngsters who have small experience but are long on memory.

In my thirty years experience I have found not one case where changes had to be made, where new equipment had to be installed or information of a complex nature was desired that the engineer could not take the time to look up details in his text books. It is quite possible that some of the examiners who are getting along in years, would themselves fail to secure the necessary number of points in such an examination. Of course the general belief is that these gentlemen have not passed such an examination under engineers outside of the examining staff at the Parliament Buildings. It is a fine thing to have a graded certificate law for engineers, but it should be a just law. I have read enough engineering literature to make hundreds of volumes, but I am thinking this law is going to be my finish for the memory test, not the knowledge or experience test, is going to put me in the "has been" class.

By all means eliminate, as chief, the engineers who will not study engineering as it is printed, for very few men can ever be safe engineers who depend upon the knowledge gained in their own operating experience only. On the other hand, give the real old engineers 1st class papers without further examination, especially so if, like myself, they held 1st class papers in 1907.

HAL BEECHER.

INDICATOR CARD CRITICISM

Editor.—Having noticed the indicator cards, published in your issue of Nov. 20th, and the criticism of same by Arthur Smith in the Dec. 5th issue, I am tempted to give my views for what they are worth.

Mr. Smith says, "She opens too soon, closes too soon, and has too much lead. Remedy put back the eccentric." He does not say what opens too soon and closes too soon, but presume he means the steam edge of the valve. This being so, the exhaust edge would be late opening and early closing. Let us go carefully over these cards and see what information they give us. We are not informed as to the type of engine they are taken from, but from the light load card should imagine it was a high speed automatic engine.

Take the left-hand card of the top, set first. Start at the extreme right-hand bottom corner, where the exhaust line starts. The line is wavy, which may possibly be a fault of the indicator. A curved back pressure line is sometimes caused by a leaky piston, but this does not seem to be the case here. The compression line starts about the normal place if anything rather late. Admission is late, shewing that there is not enough lead. It will be noticed that the vertical line slopes upward, and at the top turns to the right with a barely perceptible rise. This shows that the piston has reached the end of the stroke before admission takes place. The steam line still further bears this out.

The line falls rapidly away, showing that the steam-port is not wide open enough to supply the steam fast enough to keep up the pressure during admission. The cut off evidently takes place at the point of the line where the slight hump is evident. Release takes place just before the expansion line crosses the compression line of the other card. The card we have ben considering, though not marked, is evidently that of the rank end.

At the head end the compression takes place slightly earlier, and near the top of the compression line, admission takes place. Lead is still slightly under that required but we get a rounded line at the top, instead of a rising line as at the opposite end. Cut off takes place later, and release is slightly earlier. The terminal pressure is a little higher than in the crank end. The cards are not bad but could be improved by making the lead more on the crank end and less on the head end. This would tend to straighten up the admission line, and make the cut-off slightly later, which would give a better distribution of steam.

It must be remembered that in an automatic engine the valves are set when the governor is at its extreme open position, giving the maximum port opening and lead. It is well to block the governor out to its extreme position for running, and see how the port openings are affected.

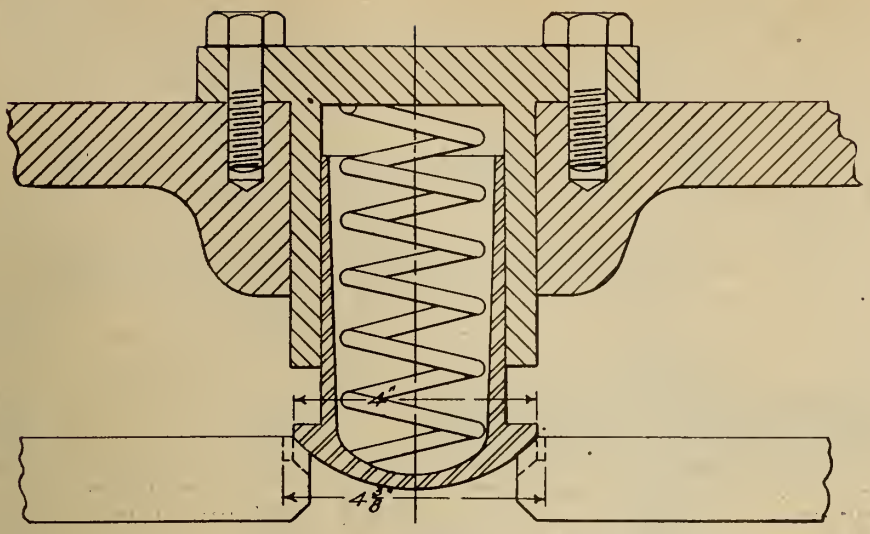
T. H. F.

SLAMMING AIR COMPRESSOR VALVES

By R. MacLaren

The discharge valves on a Brown aid compressor slammed so severely that it was impossible to sleep in the engine room. An examination showed that while originally the valve seats were flush with the valve deck through repeated refacing and wear, the seats were lowered about ⅛ in. below the surface of the deck as shown by the dotted lines in the sketch.

As the outside diameter of the seat was only a trifle greater than the outside diameter of the valve, little or no air could escape until the valve had lifted above the deck. As the ports are 3½ in. diameter and the outside diameter of the valve 4 in., and the receiver pressure 15 pounds, there would be about 44 pounds more pressure on the discharge side of the valve than on the face when the cylinder pressure reached



AIR COMPRESSOR VALVE

15 pounds, leaving the spring pressure out of the question.

To balance this air pressure the cylinder pressure had to rise to about 19½ pounds. As soon as the valve would leave its seat the 19½ pounds per sq. in. would be exerted on the entire area of the valve, with the result that the valve would be slammed back against the stop. To remedy the trouble the deck surrounding the seat was bored to a diameter of 4⅜ in. with very agreeable results.

STRENGTH OF FURNACES IN VERTICAL BOILERS

John S. Watts

THE regulations for the construction and inspection of boilers, section 63, call for "all furnaces over 42 ins. diameter, to be stayed in accordance with the rule for flat surfaces." In my opinion, formed by a long experience in building, repairing and operating boilers, this rule should be amended; as it compels the fitting of screwed stays where they do more harm than good, for the following reasons.

They tend to prevent the circulation of the water in the already confined water space around the furnace, and retain the scale and feed water deposits on the furnace plate, just where the heat is most intense. This tends to cause overheating of the furnace plate, and defeats the very object for which the stays are fitted.

A furnace without screwed stays will, if weakened by overheating or corrosion, give warning of its dangerous condition by bulging, which will warn even a careless operator that the boiler is in a dangerous condition, in time to take measures to avert the impending collapse.

On the other hand, a furnace fitted with screwed stays, will hold out, without visible signs of distress, until the plate ruptures suddenly, and a disastrous explosion occurs. This danger is accentuated by the fact that it is practically impossible to provide for thorough cleaning of the scale from the furnace shell of a vertical boiler, or to inspect it for corrosion or pitting internally.

The longitudinal expansion of the furnace shell plate is much greater than that of the boiler shell, especially in vertical boilers, the majority of which are not lagged. The screwed stays impede the free expansion of the furnace longitudinally, and the strain thereby imposed upon causes serious grooving of the furnace plate around the stays, this actually weakening the furnace instead of strengthening it, and materially shortening the life of this part of the boiler which is the most expensive part to renew.

In my experience with vertical boilers, I have never yet seen a stayed furnace cut out of a boiler, that was not badly grooved around the stay bolt holes, and generally this grooving or corrosion, reached to such a depth, as to cause one to wonder how the furnace ever held the pressure.

So far as I know, the only argument advanced in favor of the fitting of screwed stays is that we have no exact formulae, for determining the resistance to collapse of a tube under external pressure. The formulae we have, being all empirical, and based upon the results of experiments, which are too few in number to be really authoratitive. Moreover, the problem is complicated by the fact, that no furnace is ever truly circular, and the strength against collapse diminishes rapidly as the tube departs from a truly circular form.

At this point, we may call for a few moments of silent meditation to try and discover how it was that those who devised these rules, and embodied in them regulations covering such minutiae as the size of the rivet heads, could miss so important a point, as it is, to have some fixed tolerance for the departure of the furnace from the truly circular form.

Another, and in my opinion, serious weakness in the rules, is that no limit is placed on the thickness of the furnace plate.

Actual experience shows that no plate in close contact with the fire should be allowed to be more than 5-8 in. thick, and then only when nearly perfect circulation and easy cleaning and inspection can be obtained.

In a vertical boiler, I would prefer to see the maximum thickness placed at ½ in. This because, as is well known, a thick plate in contact with the fire, or very hot gasses, will soon burn or corrode away, until its thickness is ½ in. or ⅝ in., so that it is evidently useless to make the plate any thicker. In fact, it is worse than useless, as corrosion once started is apt to continue.

Now, "revenons a nos moutons": I would suggest that the rule under discussion be amended so as to allow the strength of all sizes of furnaces to be calculated by the formulae given in that rule at section 63, viz.:

$$B = \frac{C \times T'}{(L_1 + 1)\ D_1}$$

and that the length of the furnace, L, in the formulae, be the unsupported length of the furnace, i.e. the length between rows of stays.

Thus, where the desired pressure cannot be obtained by using the maximum allowed thickness of plate (½ in. in vertical boilers, ⅝ in. in horizontal type), one or more rows of stays would be fitted. The length, L, in the formulae, will then become the length from the center of the rivets, in the end seams of the furnace, to the center of the row of stays, or, the distance between the rows of stays, if more than one row is necessary.

This proposed amendment to the rule will demand screwed stays in large furnaces and for high pressures, and it may seem illogical to recommend it, after what I have said above about the grooving caused by their use. But there seems to be no better way available to gain the required strength, and the proposed rule cuts down the ill-effect of their use to the minimum.

We gain in actual strength from the fact that when stays are required by the new rule, the number to be fitted will be only about one quarter of the number demanded under the old rule. This much smaller number of stays will offer correspondingly less resistance to the circulation of the water, and to the expansion of the furnace, and therefore be less apt to set up grooving. Particulars so at the upper end of the furnace, where the expansion being cumulative from the bottom up, the amount of movement of the furnace relative to the shell is greatest. Because there will then be some two or three rows of stays, now used to stay the upper part of furnace, omitted.

But the main advantage is that, by having only one or two rows of stays, with a space of two or three feet between the rows, the furnace can, if overloaded, give warning of its condition by bulging, which it cannot do if stayed as a flat surface.

As to the safety of this rule, I cannot see why, if the rule now in use is safe for furnaces up to 42 in. diameter, as the regulations claim it is, it should not be safe for all diameters. The formula used is based on Fairbairn's rule, and he placed no limit on its scope. The British Board of Trade, and the Dominion Government laws for marine boilers, give practically the same formulae, but make no restrictions as to the diameter of the furnace, such as have been embodied in our Provincial statute.

New Lodge C. A. S. E.

Stationary engineers organized at Hanover, Ont., on October the 28th. President Bro. Moll had the pleasure of organizing a branch lodge of the C.A.S.E. No. 38, at Hanover, Ont., installing the following officers: president, Charles Falconer; vice-president, Wm. Zufeldt; recording secretary, Ed. Holler; treasurer, Chris Weis; financial secretary, Thos. Scott; conductor, Jas. Martin; door-keeper, J. J. Lang. After installing the officers and instructing them for their work, a lunch was served, after which a hearty vote of thanks was tendered to Bro. Moll for his great interest in the C.A.S.E.

Peeble's Medium and Slow Speed Alternators.

Bruce Peebles & Co., Ltd., Edinburgh, Scotland, have issued pamphlet No. 13-C, dealing with medium and sloow speed alternators. This pamphlet gives a full specification of the machines, together with a number of half-tone illustrations, also lists of ratings for 50- and 25-cycle alternators for all pressures from 200-6600 volts, a rule being given for working out the ratings of machines of other periodicities.

A New Bulletin.

"Dunham Heating Date" has just been issued, describing and explaining standard methods of figuring radiation and laying out piping. Valuable ventilating data is also included, the whole being put in very practical and concise form, getting at the real information without having to wade through a lot of preliminaries. Various details of piping connections are illustrated, and complete pipe sizing information given. This bulletin, together with several others of interest and value to the stationary and heating engineer, can be secured by writing the C. A. Dunham Co., Ltd., 1535 Davenport Road, Toronto, Ont.

Live Steam is Money—Don't Let It Escape

It takes coal to generate live steam and it costs good hard-earned dollars to buy that coal—more of those dollars than it ever cost before.

Therefore, every bit of live steam that escapes from your steam trap means money out of your pocketbook.

Keep that money in your pocketbook. If you have any steam leaking around your plant rip them out and put in the Steam Trap Sarco. It positively does not leak live steam. That we guarantee when properly adjusted. You can prove this to your own complete satisfaction in the 30 days' free trial we give you on the

Steam Trap Sarco

Its knife edge blade absolutely prevents the loss of a single cent's worth of steam from one end of the year to the other.

Steam Trap Sarco operates hydraulically. The reliable expansion and contraction of a sensitive expansion element controls the valve. It drains off all condensation as soon as it is formed.

And it is so simple that it will outlast other traps. It has no complicated system of levers, gauges, etc., to get out of order and wear out. There is only one moving part.

Furthermore the Steam Trap Sarco costs less than 1-3 the price of other traps. And it costs less to install because no building up, no supports and no floor space are required. Without changing the piping, it can be quickly installed at any angle, at any point on the line.

Guaranteed for any given pressure up to 200 lbs. Made in sizes ¾" to 3".

Send for our booklet "J."

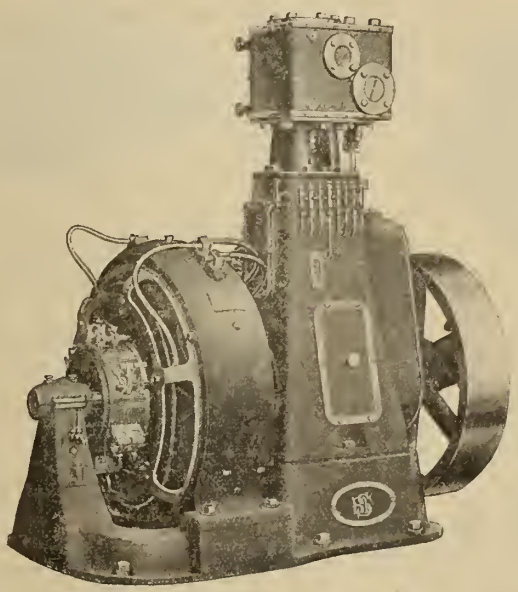
Sturtevant

TRADE MARK

Electric Generating Sets



Designed and Built to U.S. Navy Specifications!

—which fact forcibly indorses their efficiency, design, dependability, and quality of construction. Have close regulation and are suitable for all light and power purposes. Specially adapted for isolated power plants, and as auxiliaries in large plants, as well as on ship-board. They are compact, self-contained units, consisting of a Sturtevant steam engine direct connected to a conservatively rated Sturtevant electric generator. Are made with automatic lubricating systems, either gravity or forced feed. All reciprocating parts of the engine are entirely enclosed within the engine frame, which is provided with oil- and dust-proof covers. All parts are readily accessible by removing these covers. Write us for Bulletin No. 239U which details the merits, design, and construction of Sturtevant Electric Generating Sets.

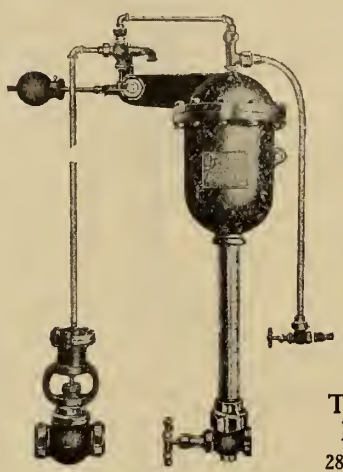
VIGILANT
Automatic Feed Water Regulator

100% Protection

3 to 17% Fuel Saving



Keeps the water within ¼ in. of middle gauge, regardless of the load or firing. Works automatically, perfectly — an absolute protection from high and low water accidents. Because proven an absolute protection and a fuel saver too, the Vigilant is used by nearly all the iron and steel producers in the States.

The Traveling Tripper For Instance

Every detail of the

Jeffrey

Pivoted Bucket Carrier

is the result of over twenty years' successful experience in designing and building economical Coal and Ash Handling Machinery.

Take the Traveling→ Tripper for Instance

The following are but a few notable features that are typical of construction throughout the JEFFREY Carrier—

1. Strong and substantial.
2. Easy bucket engagement, with assured emptying of buckets, and a gentle release by the Tripping Cams.
3. Tripping Cams with thick wearing surface, deep chilled, hard as flint, for long service.
4. Tripping Cams readily lowered by racks and pinions so that Tripper may be shifted quickly when the Carrier is idle or when a Stationary Tripper is in service.
5. Tripper so balanced that little effort is required to move it in either direction when the Carrier is in motion.
6. Release ends of Tripper Cams adjustable for easy release of the buckets.

Our Engineers will gladly point out to you all the advantages of the JEFFREY Carrier. Write to-day for our new Catalog No. 210.

Make it Easier--

ALL-WAY
Flexible Spout
Grease and Oil Guns

Make it easy to refill the most out-of-the-way gear cases or transmission as the flexible spout can be bent to any desired angle. The Cleaning Device at the end of the **"ALL-WAY"** spout reduces cleaning time and oil wastage to a minimum.

The **"ALL-WAY"** gun is especially useful and handy in filling lineshaft hanger reservoirs.

If your dealer cannot supply you, write us.

We also manufacture the well-known "ALL-WAY" Oil Can. Saves you 50% of your oil bill.

Mason Reducing Valve installed in the Protestant Hospital for Insane, at Verdun, Montreal.

1896 to 1919

Mason Reducing Valve On the Job 23 Years

In spite of the fact that the Mason Reducing Valve pictured above has seen 23 years of wear it is giving as good service now as the day it was installed, and is fit for another 23 years or more. Long and satisfactory service and minimum upkeep cost is common to GENUINE MASON Valves. Supplied by all dealers and jobbers.

Must School Teachers Starve?

By Sir Robert Falconer, President of the University of Toronto

CANADA is threatened with another epidemic—cheap teachers! A grave warning, showing the seriousness of the situation, has been made public, through the medium of MACLEAN'S MAGAZINE.

The financial attractions in commerce and trade are proving such a lure to the clever Normal School and University graduates that public schools, high schools and universities throughout the Dominion are being driven to engage inferior teachers—if they can get any at all! One teacher in Ontario is paid the princely sum of $300 per annum.

The article gives the opinions on this vital topic of such men as: Sir Robert Falconer; Principal R. Bruce Taylor, of Queen's; Dean of Arts W. Sherwood Fox, of Western University; A. P. S. Glassco, Secretary of McGill; President MacLean, of the University of Manitoba; President Klinck, of Canada's youngest university—British Columbia; President A. Stanley Mackenzie, of Dalhousie; and many others.

"The Thread of Flame"

By Basil King

This famous Canadian novelist has written a remarkable story that deals with a man who loses his identity while fighting in France. This strong novel, "The Thread of Flame," starts in the December issue of MACLEAN'S. This is the first occasion that a novel by Mr. King has appeared in any Canadian periodical prior to book publication.

Other Features of the December Number

"Merrie Gentlemen"—By Arthur Beverley Baxter.
You will think this the best Christmas story since Dickens' "A Christmas Carol."

"Capital and Labor"—By Ralph Connor.
One of a series of articles on "The New Canada and Its Needs."

"Ottawa is Ready for the Worst"—By J. K. Munro.
A humorous and pithy review of events at the Federal seat.

"Better Late Than Never"—By C. W. Stephens.
A bright Christmas story.

"Some Canadian Snobs"—By Montgomery Dix..
A humorous article on some phases of Canadian society.

"A Blighty Christmas"—By Gertrude Arnold.
An article on the way Yuletide was celebrated in a Red Cross Hospital.
And a dozen other articles and stories all of equal interest.

MACLEAN'S will be Twice-A-Month

starting February 1st, next year. An important point to remember. If you want to keep up with things **nationally Canadian,** you'll have to get the MACLEAN'S Twice-A-Month habit.

Over 350,000 Canadian Read

MACLEAN'S

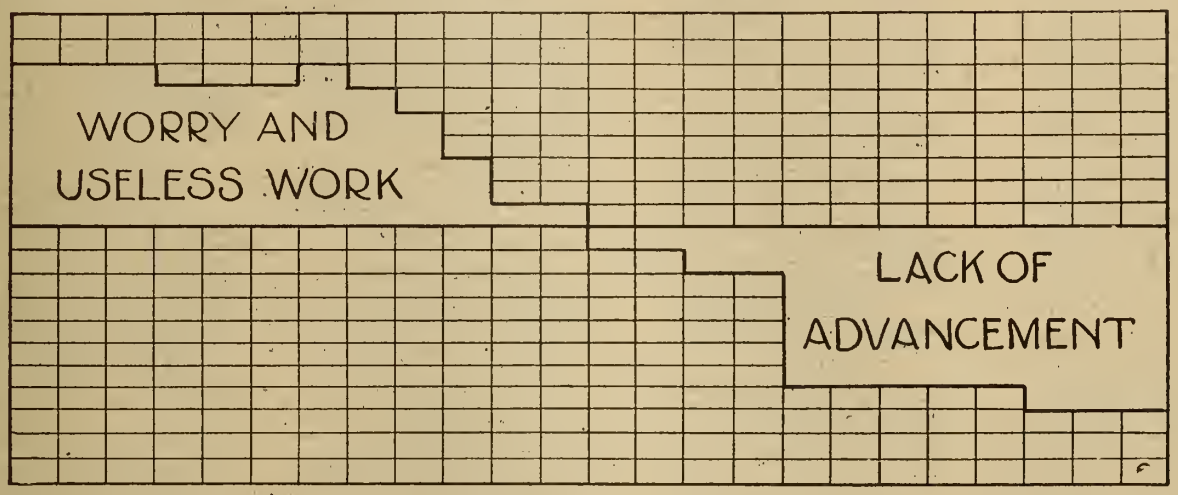
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

STARRETT HIGH SPEED INDICATOR No. 104, Value $1.00 Given for two yearly paid-up subscriptions.

You May Have This Speed Indicator without Spending a Cent

if you are a subscriber to "POWER HOUSE." If you are not a subscriber, send in your own subscription together with two others, and the indicator you are entitled to will be mailed to you immediately.

To subscribers who send us two NEW yearly paid-up subscriptions we will send this $1.00 indicator.

"POWER HOUSE" is designed to give Canadian Engineers, Superintendents and Power Users all the latest and best information in the engineering field. A little work among your engineer friends and acquaintances will earn for you this handy indicator without any trouble. Try it and see how easy it will be.

PUBLISHED SEMI-MONTHLY AT $1.00 PER YEAR

ECONOMIC Carling BLOWERS SUPERIOR

Carling Turbo Blowers

For burning the lowest grades of coal successfully, getting all the heat value from the fuel. For positive draft with Automatic Control and steady steam pressure. For obtaining the ultimate capacity from the boiler.

Carling Blowers are low in first cost, easy to install and make a quick return on the investment. We will be pleased to show you why it pays to use Carling products.

Write to-day. Try at our expense.

Davies Packing Co.
Harris Abattoir
Canadian Kodak Company
Hinde & Dauch Paper Co., Limited
Consumers Gas Co. (3 plants)

THE McDONOUGH DAMPER REGULATOR

This Damper Regulator saves $300 per boiler annually in many plants. It will on ½-lb. variation regulate Dampers, Stoker Engines, Stoker Motors, Forced Draft Engines, Gas Supply to Boilers. We put in the Quality before we put on the name.

We install this Damper Regulator in your plant for 30 days' trial, free of cost to you.

THE FEED WATER REGULATOR

We know positively that this Feed Water Regulator does what other Regulators try to do—maintains a flow of water to your boilers at the exact rate it is being evaporated into steam, that means boilers give drier and more steam for less money than is possible with other Regulators.

Two Good Reasons WHY:

Pittsburgh, Pa., Sept. 19, 1918.
We have your letter of August 9th and wish to advise you that we have your Automatic Regulator installed in our power plant, in this city.
We have been keeping record of the coal used in anticipation of this installation, and find that we have an actual saving in coal alone of twenty-five (25) per cent. for the past three months, with considerable of an increase in our factory production.
JAS. H. MATHEWS & CO., INC.,
(Sgd.) Jas. H. Mathews, Pres.

TORONTO, November 17th, 1919.
"We have had the McDonough Automatic Damper Regulator System and Feed Water Regulators System in use for more than six years in our Old and New Plants and we are pleased to state that these two controlling systems have been satisfactory and we find same a great fuel saving equipment giving us steady water level in our boilers and a steady head of steam as well. We will be glad to recommend these controlling systems to prospective purchasers of steam plants."
THE WM. DAVIES CO., LTD.,
(Sgd.) J. C. GILLIES, Mech. Supt.
